Oh Neil, where out here! What's going on with the new 1200 buad
modem? Also I heard a rumor that you could upgrade the 1030 modem to
1200 baud. Any comments.

###########...Purina Line Eater Chow...###########

Has anyone tried to use the 65802 in an Atari 400? I have been thinking of giving it a shot, because of the added instruction capability. I understand that it is compatible with the existing 6502. Has anyone verified this? On the smaller side, I have also heard that the 65C02 will work in the 400/800, but not the newer 800XL and XE models. Verification?

Also, I have need of a serial interface board for my Atari. Since my Atari is mainly used for fun, I was thinking of constructing one of my own from scratch, that will sit on the serial line and provide support for at least two RS232 ports. Has anyone got a good design for one? I am trying to work out a way so that the RS232 controller will be smart enough not to interfere with the disk I/O requests. I would prefer to allow RS232 I/O and disk I/O over the same channel without specially toggling the RS232 line off the serial bus. Still, if anyone has any brilliant ideas of how to build any sort of serial interface for the Atari that interfaces through the serial bus, drop me some mail.

I don't think you are quite right about this. There is no code in Dos 2.0
to treat the first three sectors of the disk specially (i.e. 128 instead of
256 bytes), so any function which writes these (format, write Dos files, etc.)
will fail. Perhaps the ATR 8000 compensates for this, and allows you to write
these sectors either way, but I am sure a regular disk drive will not do this.

It does seem like a crying shame, since someone certainly went to a lot of
trouble to put 95% or more of the code for double density support into Dos 2.0.

Hmmm... in that case why not get a Happy upgrade. It will make a 1050
double density and can be completely disabled if need be.
It supports full track buffering, warp speed, single/double/1050 density
You do not need special OS ROM's
I've had one for a while and I'm very 'HAPPY' with it.

What I failed to include was the information that the first three sectors must be 128 bytes ONLY regardless of their density AND the drive MUST switch densities by itself (yes--the ATR8000 does the 'switching'). This concept was first implemented by PERCOM who used to make drives for many of the home micros, including ATARI. When Rana came on the scene they implemented the same idea (I also had one of those at one time). The real proof, of course, is to insert a double density disk and see what happens. The various DOSes like MYDOS, SMARTDOS, etc have the capability to create a double-density disk with a DOS on it. DOS 2.0, tho, won't do that.

So how can you get a double-density disk with DOS 2.0?

I did it in the past with a PD program circulated by PERCOM, but they went out of the ATARI drive business. BUT, if someone really wants a double-density DOS 2.0, I will try to find the program and post it (if I can figure out how to do that!).

7. Need Programming Help

Newsgroup: comp.sys.atari.8bit
Date: 1986-12-06 19:25:21 UTC
From: rmrin@inuxa.UUCP
Message-ID: <219@inuxa.UUCP>
Source record: 118011

Hello World (oops, wrong book),
I'm finally finding some time to play
with a few of the goodies that come
past here but I need a little help.
I down loaded a very long game file
but since it was to big for my machine's
buffer and direct to disc always gives
errors, I split it into two files and
downloaded each seperately (I'm talking
hexadecimal file stuff). I never did
figure out how to put the files together
using DOS 2.5 but with DOS 3.0 it
worked, sort of. Unfortunately now
I have a very long hex file with a
line right in the middle which says

$

(that's a system prompt and then
probably a line feed).
When I convert the file, it starts up
fine but the screen goes back to the
startup before one can play (It's the
game like concentration). I suspect
my problem is that spurious line feed
(In fact I'm amazed that it didn't
cause the whole thing to bomb).
I'm using an 800XL and standard atari
disc drives. The modem is a smart
modem, if that makes any difference.
My first question is how do I edit the
big file to get rid of that "$"?
My second question is how could I have
joined the two files using DOS 2.5?
Helpful hints much appreciated.

Yeah, there are users out here. Neil, what's happening with the XEP-80?
Same with 1200 baud modem.

Also anyone out there using 256K 800XLs? Like with extram mem is great.
We are currently attempting to modify a unsocketed machine. So far it's
been a big pain. Anyone who has experience with it, comment please.

Message-ID: <7582@topaz.RUTGERS.EDU>
Source record: 118013

```
To edit the file you can use any text editor (Atariwriter, Paperclip,
etc.) To append the two files use the 'C' command from the DOS menu.

example:
C
file2,file1/a

Hope this helps.

Does anyone know of any 80 column word processors for the Atari
8-bits? I don't mean just a "preview" mode, but actual 80 column
on-screen editing (achieved through a graphics 8 character set?).
If there are any that exist, how good are they?

Ray Wilmott
wilmott@topaz.rutgers.edu

12. termcap and BASIC program

Newsgroup: comp.sys.atari.8bit
Date: 1986-12-08 17:23:37 UTC
From: flynn@cory.Berkeley.EDU
Message-ID: <1253@zen.BERKELEY.EDU>
Source record: 118016

I posted an article recently saying
that I had a termcap and BASIC program
for the PR connection. I got a lot of
response to that then realized that I
had been a little misleading. First,
it should not be restricted to PR
owners, as I know of no reason why it
shouldn't work woth the 850 also,
since the PR-connection is supposed to
behave like the 850.

To be specific, here is a fuller des-
cription of the stuff I wrote. It
is a termcap that has parameters for
all the stuff needed for vi, and talk,
and stuff like that so the atari acts
like a real terminal (with 40 cols.).
The BASIC program is not fancy, but
good enough for a starter. It dials (
but my modem is not HAYES-compatible,
so the program could easily be simp-
lified for HAYES) and it captures and
sends files, but mostly it just acts
like a terminal.

Chances are you are only interested in
using the termcap and the few routines
in the BASIC program associated with
that so vi can behave properly on your
old friend 800.

Any interest in any of this, respond
to:
flynn@cory.Berkeley.EDU
OR if that fails
erich@cory.Berkeley.EDU
OR
varian!madvax!karenmad@lll-crg.arpa

In mailing, use "atari" in the Subject

No, you cannot upgrade the 1030 to 1200 baud. ANALOG printed this misinformation a couple of years back.

The 1200-baud modem should be out early in the year.

Greetings,
For reasons not worth getting into, I stopped using my Atari 400 and sold it,
about two years ago.

Now I have an 800 XL W/1050 Disk Drive. In an old Antic, I came upon some
SW to build an autorun.sys file on my disk. Using DOS 2.5 I typed it in,
and followed the directions. It does work, but not as advertised.

The problem is, when I cycle the power, the load begins and then stops. After
I type a return, the load resumes and loads/executes the program. Is there a
newer version of this utility that does not stop? Could someone please
either mail or post this? Thanks in advance,

15. Re: questions (about double density DOS 2.0)

Newsgroup: comp.sys.atari.8bit
Date: 1986-12-09 14:53:30 UTC
From: kmeis@drupa.UUCP
Message-ID: <949@drupa.UUCP>
Source record: 118019

Whenever I want to create a double density version of dos on my Percom,
I set one drive to double density, boot up on the other single density drive,
go to DOS and use the write DOS option. As soon as you write DOS to the
double density drive you can boot with it. It is my understanding that
DOS 2.0 was created with Atari's never released double density drive in mind
and it is therefore compatable with double density. (I am, however, not in
front of my Atari, so I can't boot to check the exact DOS version number).

16. Turbo Basic for XL's Part 0/2

Newsgroup: comp.sys.atari.8bit
Date: 1986-12-09 16:20:16 UTC
From: oaa@houxl.UUCP
Message-ID: <1054@houxl.UUCP>
Source record: 118020

I would like to start posting some programs to the net that appeal
to the general audience out there.

I assume that people have access to local BBS where they can obtain
programs, so there is no need to post some of the more popular public
domain programs. I also assume that not everyone accesses the net
through a UNIX computer or other large computer so I should not use
"uuencode" or "arc" to encode binaries. If I am incorrect on these
points let me know.

I would like to start by posting a program called "Turbo Basic-XL".

Apparently it's a public domain program from somewhere in Europe
that provides a Basic interpreter that's 100% compatible with
Atari Basic and provides many new and valuable features including:
many new commands and functions, faster execution of programs (3
times faster, so you can tolerate using some of those Basic games),
and a little more available memory. It's basically similiar to
Basic-XL or Basic-XE from OSS.

The only bad part is that it only works in XL and XE machines.
(An 800XL is really an excellent buy for Atari owners at ~$70,
and with 256K ram added a real joy to use.)

I'll post the docs and binary separately. I'll use BINHEX to
encode the binary since that will work for just about everyone.

Here is the docs for Turbo Basic, binary will follow in BINHEX format.

Owen Alexander
========= Cut Here ============

TURBO BASIC COMMAND LIST

Compiled and Translated by
Dave and Laura Yearke

This documentation is provided by the Western New York Atari Users
Group and may be reprinted freely provided this credit is included.

In case you've just landed from Mars, or just plain haven't heard
yet, TURBO BASIC is the exciting new Public Domain Basic Interpreter that
we received from the Atari Users Group in Holland. It works on the XL or
XE series of Atari computers. It's almost too good to be true and should
be a definite must for all XE or XL Atari owners.

Turbo BASIC, in addition to offering 42 more commands and 22 more
functions than Atari BASIC, gives the user 1603 more bytes of program
space by "hiding" part of itself under the XL/XE's operating system. It
also runs 3 times faster than Atari BASIC, includes most DOS commands,
has advanced graphics and programming functions, and is insensitive to
lower case or inverse characters for most commands.

TURBO BASIC COMMANDS:
====================

Name Syntax Description

Disk I/O

BLOAD BLOAD "D:name"

Binary loads file name (DOS option L with /N).

BRUN BRUN "D:name"

Binary load and run file name (DOS option L).

DELETE DELETE "D:name"

Deletes the file name (DOS option D).

DIR DIR

Disk directory (DOS option A).

DIR "Dn:*.*"

Directory of drive #n, note that wildcard extenders may be used.

LOCK LOCK "D:name"

Locks the file name (DOS option F).

RENAME RENAME "D:old,new"

Renames the file name (DOS option E).

UNLOCK UNLOCK "D:name"

Unlocks the file name (DOS option G).

Graphics

CIRCLE CIRCLE x,y,r

Plots a circle with center at x,y and radius r.

CIRCLE x,y,r,r2

R2 is an optional "vertical radius" for true circles or ellipses.

CLS CLS

Clears the screen.

CLS #6

Clear screen opened in channel 6.

FCOLOR FCOLOR n

Determines fill color.

FILLTO FILLTO x,y

A fill command analagous to the BASIC commands "POSITION x,y: XIO 18,#6,0,0,"S:"

PAINT PAINT x,y

Another type of fill command, this one is a recursive routine that will fill any closed object as long as x,y are inside it.

TEXT TEXT x,y,a$

Bit-blocks text in a$ at x,y.

Memory

DPOKE DPOKE m,v

Pokes location m,m+1 with 2-byte integer v: (0 <= v <= 65535).

MOVE MOVE m,m1,m2

Block transfer; moves m2 (number of bytes) from starting position m to new starting position m1.

-MOVE -MOVE m,m1,m2

Same as MOVE but copies starting with the last byte of the block.

BPUT BPUT #n,adr,len

Block Put; same as: FOR I=0 TO len-1:PUT #n,PEEK (adr+I):NEXT I

BGET BGET #n,adr,len

Block Get; same as: FOR I=0 TO len-1:GET #N,A:POKE (adr+I):NEXT I

%PUT %PUT #n,a

Until now, there was no convenient way to put numeric values onto disk or cassette files other than by using PRINT, which converted them to strings first, a slow and cumbersome process. %PUT puts the number to the device "as is," in 6-byte FP format.

%GET %GET #n,A

Get a number stored with %PUT from the device and store it in variable. Again, this is much faster than using "INPUT #n, A".

Structured Programming

REPEAT REPEAT

Start a REPEAT-UNTIL loop.

UNTIL UNTIL <c>

Terminate when condition <c> met.

WHILE WHILE <c>

Start a WHILE-WEND loop to end when condition <c> met.

WEND WEND

Terminate a WHILE-END loop.

ELSE ELSE

Optional extension for IF. The IF condition must not be followed by a "THEN", but terminated by end-of-line or colon.

ENDIF ENDIF

Ends an IF-ELSE-ENDIF or IF-ELSE condition. Note that this allows an IF condition to span more than one BASIC line, provided the "IF" statement is structured as shown in Note 5.

DO DO

Starts an "infinite" DO loop.

LOOP LOOP

Cycle back to the start of a DO loop.

EXIT EXIT

Exit a DO-LOOP loop.

PROC PROC name

Start definition of procedure.

ENDPROC ENDPROC

End definition of procedure.

EXEC EXEC name

Execute procedure name.

General Programming

PAUSE PAUSE n

Pause processing for n/50 seconds.

RENUM RENUM n,i,j

Renumber the program starting at line #n, first number is #i, increment is #j. This function will handle GOTOs, TRAPs, and all other line references except those which involve variables or computed values.

DEL DEL n,i

Delete lines n-i.

DUMP DUMP

Display all variables and values. For numeric arrays, the numbers are the DIMed values plus one. For strings, the first number is the current LENgth of it and the second number is the DIMed size of it. DUMP also lists procedure names and labels with their line values.

DUMP name

DUMP to device, such as "P:" or "D:DUMP.DAT".

TRACE TRACE

Trace program during execution.

TRACE -

Turns trace mode off (Default).

DSOUND DSOUND n,f,d,v

Form of SOUND which activates channel-pairing for increased frequency range.

DSOUND

Turns off all sounds.

GO TO GO TO n

Alternate form of GOTO.

*L *L

Turn line-indent on (Default).

*L -

Turns line-indent off.

*F *F (or *F +)

Special mode for FOR..NEXT loops which corrects a bug in Atari BASIC. Seems that in Atari BASIC, an "illegal" reverse loop like "FOR X=2 TO 1:PRINT X:NEXT X" will execute once even though the condition is met initially (X is already greater than 1). Turbo BASIC fixes this bug, but leaves it available for Atari BASIC programs which may take advantage of it.

*F -

Turns off the special FOR..NEXT mode to make Turbo BASIC act like Atari BASIC.

*B *B (or *B +)

Command which allows the break key to be trapped via the "TRAP" command within a program.

*B -

Turns off the special BREAK key mode.

-- --

Special form of REM which puts 30 dashes in a program listing.

Line Labels
---

name

Assigns the current line number to the label name. This is a convenient way to get around the problem of renumbering when using variables as line numbers. Labels can be thought of as a special form of variable, as they occupy the variable name table along with the "regular" variables. We also believe that the number of variables allowed has been increased from 128 to 256 to allow for the addition of these labels.

GO# GO# name

Analagous to the GOTO command.

Modifications

CLOSE CLOSE

Close channels 1-7.

DIM DIM a(n)

Will automatically assign a value of zero to all elements of the numeric array being dimensioned, and null characters to all elements of a string (The LEN is still variable, however, and initially zero).

GET GET name

Wait for a key press, assign the value to name. Same as "OPEN #7,4,0,"K:":GET #7,name:CLOSE #7".

INPUT INPUT "text";a,b...

Prints text as a prompt before asking for variable(s), same as Microsoft-BASIC.

LIST LIST n,

List program from line #n to end.

ON ON a EXEC n1,n2,...

Variation of ON...GOSUB for procedures. N1, n2 and so on are names of procedures to be run. ON a GO# n1,n2,... Similar to ON...GOTO except that line labels are used instead of line numbers.

POP POP

This command now pops the runtime stack for all four types of loops.

PUT PUT n

Same as "PRINT CHR$(n)";

RESTORE RESTORE #name

Restores the data line indicated by the label name.

RND RND

Parentheses are no longer needed at the end of this command, but it will still work if they are there.

SOUND SOUND

Turn off all sounds.

TRAP TRAP #name

TRAPs to the line referenced by the label name.

TURBO BASIC FUNCTIONS:
======================

Arithmetic/Logic

HEX$ HEX$(n)

Convert n to hex string.

DEC DEC(a$)

Convert hex string A$ to decimal.

DIV n DIV i

Integer quotient of n/i.

MOD n MOD i

Integer remainder of n/i.

FRAC FRAC(a)

Fractional part of a.

TRUNC TRUNC(a)

Truncates fractional part of a.

RAND RAND(n)

Generates random number 0-n.

$ $nnnn

Allows input of hexidecimal numbers, but they are converted to decimal.
Ex: "FOR I=$0600 to $067F" => "FOR I=1536 to 1663".

& n & i

8-bit boolean AND.

! n ! i

8-bit boolean OR.

EXOR n EXOR i

8-bit Exclusive-OR.

Memory

DPEEK DPEEK(m)

Double-PEEK of m,m+1.

TIME TIME

Time of day (numeric).

TIME$ TIME$

Time of day string, HHMMSS. Unfortunately, the time commands don't work
properly because they were written for European Ataris which operate at
50 Hz, instead of 60 Hz like American ones, the net result being that
they gain 12 minutes each hour.

INKEY$ INKEY$

Returns last character typed.

INSTR INSTR(x$,a$)

Returns relative location of start of string A$ within X$ (returns 0 if not found). The
match must be exact; strings with the same letters but differences in case or type (normal
or inverse) will not be found.

INSTR(x$,a$,i)

i specifies the starting point of the search.

UINSTR UINSTR(x$,a$)

Same as INSTR, does not distinguish between case or inverse characters.
Ex: UINSTR("HeLlO","hello") returns 1.

UINSTR(x$,a$,i)

Specifies optional starting point.

ERR ERR

Value of last error number.

ERL ERL

Line last error occurred at.

Constants

%0
%1
%2
%3

These four constants simply stand for the numbers 0-3, respectively.
The difference with using these in a program is that "X=1" requires 10
bytes, whereas "X=%1" only needs 4. (Numbers require 7 bytes, 6 for the
number plus an identifier preceding it. It is always a good practice to
make variables for numbers that are used more than three times in a
program).

NOTES:
=====

1. Variable, Procedure and Label names may contain the underscore (_) character.

2. To print a double-quote (") in a text string, use two of them together, instead of the Atari BASIC method of using CHR$(34). Ex: "TEST";CHR$(34);"TEXT" becomes "TEST""TEXT" in Turbo-BASIC, both of which produce the output => TEST"TEXT.

3. Upon initial boot-up, TURBO-BASIC looks for a BASIC file named AUTORUN.BAS. If it finds an AUTORUN.BAS file, it will automatically load and run this file.

4. Turbo-BASIC also prints out English descriptions of all errors, including several new ones for errors involving the new commands:

Error - 22 ?NEST = Loops not properly nested.
Error - 23 ?WHILE = WEND with no corresponding WHILE.
Error - 24 ?REPEAT = UNTIL with no corresponding REPEAT.
Error - 25 ?DO = LOOP with no corresponding DO.
Error - 26 ?EXIT = EXIT is outside a loop.
Error - 27 ?XPROC = Error executing PROC.
Error - 28 ?EXEC = ENDPROC with no corresponding EXEC.
Error - 29 ?PROC = Procedure does not exist.
Error - 30 ?# = Label does not exist.

Also, Error 15 has been expanded to include an UNTIL which relates to a REPEAT which has been deleted.

5. A multiline IF is constructed like this:

```
10 IF X > 10
20 PRINT X-10
30 GO# TOO_BIG
40 ELSE
50 PRINT X
60 GO# X_IS_OK
70 ENDIF
```

Note also the use of line labels in the GOTO statements.

19. Re: 80 col. word processor

Newsgroup: comp.sys.atari.8bit
Date: 1986-12-10 23:25:38 UTC
From: btb@ncoast.UUCP
Message-ID: <1809@ncoast.UUCP>
Source record: 118023

I have seen an 80 col word processor for the 8-bits advertised in Antic before... I think the program is called "Richman's Word Processor"... I regularly use a simulated "80-col" vt100 emulator... in fact I'm using it right now with vi to write this, and it is definitely liveable... I also have the Chameleon terminal emulator which scrolls... Chameleon is good, but for scanning text, it is a real pain to have to scroll horizontally... this simulated 80-columns is ok to read... obviously not sharp and crisp.. and often ambiguous, but you can figure things out from context... amazing the way the mind works... (=> not good for exacting work like creating data files, though, eh?)

21. Turbo Basic for XL's 2/2

Newsgroup: comp.sys.atari.8bit
Date: 1986-12-11 15:29:11 UTC
From: oaa@houxl.UUCP
Message-ID: <1058@houxl.UUCP>
Source record: 118025

Here is the binary in BINHEX format. Use binhex.bas program
posted several months ago to decode into a binary file.

Don't forget to convert ASCII eol to ATASCII eol.
On Unix use: tr "\233" "\012" <asc_file >ata_file
then x-modem download ata_file to your Atari
On Atari: Capture the file (automatically converts eol)

23. RE: Info-Atari8 Digest V86 #11

Newsgroup: comp.sys.atari.8bit
Date: 1986-12-11 22:36:41 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8612112236.AA08260@mitre-bedford.ARPA>
Source record: 118027

The following question was included in a recent Atari8 Digest:
>"Also anyone out there using 256K 800XLs? Like with extram mem is great.
>We are currently attempting to modify a unsocketed machine. So far it's
>been a big pain. Anyone who has experience with it, comment please."
> "Arnold
> ADELEON@HMCVAX"
I thought that the following reply might be of general interest to the Net,
especially the fairly detailed instructions on removing IC chips.
-John S.
============

I have been using a Newell 256KXL board with CDY's OMNIVIEW256 for many months
now and it is hard to imagine how people get along without big buffers and
RAMdisks. It is especially nice to have the convenience of a RAMdisk that is
resident in the machine itself (in OMNIVIEW256) because it works with
absolutely any DOS just as though you really had another disk drive.
(But of course a zillion times faster than a real disk drive.)
The built-in 80-column capabilities you get with OMNIVIEW and CDY's nice
application software like OmniCom and OmniWriter (80-column Terminal Emulator
and Word Processor, respectively) don't hurt a bit, either. Also it's a
pleasure to never need the "Translator Disk" again!

As for unsocketed machines, yes, it is a pain to have to remove the memory
chips, but it can be done safely and easily IF YOU TAKE THE TIME TO LEARN HOW
AND GET THE RIGHT EQUIPMENT FIRST. I recommend that you get the following
things before attempting the job:

1. A good low-wattage soldering iron like an Ungar with about
a 30 to 40-watt, small sized tip.
2. A "Solder Sucker" or "Soldapullt" vacuum-generating device
to remove excess solder.
3. A roll of "Solder-Wick" to soak up the last little bit of
solder.
4. A roll of Ersin Multicore 60/40 solder or other high-quality
solder (but if it's not Ersin or maybe Kester, you are
on your own, Buster).

The thing to remember is that the BIGGEST DANGER is that you will overheat the
etched wiring and cause its adhesive to fail so that it comes loose from the
board. If that happens you will either have a badly botched-up board or else
you will have a brand-new board, at YOUR EXPENSE. So above all, KEEP IT
COOL!!! Use the least amount of heat you can get away with. This means using
every other trick in the book to make the job go smoothly with little applied
heat.

If you don't need the chips (e.g. 64K RAM chips) then they are a throwaway item and the SAFEST thing you can do is to snip off all their pins at the top with a pair of "dikes" (diagonal side-cutting pliers). Then take a pair of needle-nosed pliers and gently pull out the snipped-off pins from the top while heating the individual pads from the foil side (the etched wiring side) of the board. With this method you need very little heat at all, because as soon as the solder on the individual pad you are working on melts, the pin pulls out easily and you can (and should) immediately remove the heat. You will still need the solder sucker or AT LEAST the Solder Wick to remove the residual solder so you can put in the new chips or sockets for them, so read REMOVING SOLDER below.

When you have gotten better at unsoldering ICs (and if you are a cheapskate like me who can't bear to throw away 64K RAM chips), then it is perfectly possible to remove the whole chip at a time. But first, you need to remove as much of the solder holding it in place as you can.

REMOVING SOLDER. First, go around the chip with your solder-sucker and soldering iron. For each pad: heat the pad carefully and (I recommend this) ADD some small amount of solder to make sure the solder is well supplied with flux and able to flow freely. AS SOON AS you have done this, ZAP the hole in the pad with your solder-sucker. (To the novices, the SoldaPullt type of gadget is a spring-loaded piston device that pops out when released and draws in a stream of air -- and solder -- at high velocity. It is VERY effective at removing solder if you have the solder heated and supplied with flux from the new solder and you release the spring at this critical moment with its intake tip right on top of the pad you are heating. It's a little tricky but not too hard to learn how to do.)

IMMEDIATELY remove the heat and inspect the hole. If you did everything right, the IC pin will be nearly free of solder and at most sticking to the hole at one point. Now you can usually free it by wiggling it or at worst do one more heating step with the Solder Wick to absorb the last vestiges of solder, then wiggle the pin loose.

Go around each chip like this until all pins on the chip are as free of solder as you can easily get them and all or most of them are also unstuck. If there are one or two holdouts, you can either repeat the process with the Solder Wick or else heat the troublesome pins once more as you pry the IC out of the board with a small screwdriver placed under one end of it and then the other. You should have the IC out of the board and both board and IC undamaged, in a minute or so per IC when you get good at this procedure. All it takes is having the right equipment and being careful to do ALMOST ANYTHING other than using excessive heat.

Once you have removed the chips, I would recommend installing sockets before putting in the new chips. Then you'll never again have to run the risk of damaging the board by unsoldering a chip in the future. Again, be careful of heat when installing either chips or sockets. Use ENOUGH but NOT TOO MUCH solder. NOTE: A good way to remove excess solder when installing chips is to heat the pads from underneath and let the excess roll down the tip of the soldering iron. Surface tension takes care of retaining just about the right amount.

If you are unusually thumb-fingered or have maniacal self-destructive tendencies, you had best let someone else remove your IC chips, but otherwise, if you follow the above instructions you will probably do just fine.

Just "KEEP IT COOL!"

-John Sangster

24. Atari 800XL (help)

Newsgroup: comp.sys.atari.8bit
Date: 1986-12-11 23:50:29 UTC
From: EatMyDust@nsc.NSC.COM
Message-ID: <3976@nsc.NSC.COM>
Source record: 118028

Hello,
I have recently purchased an 800XL, it came with almost no documentation.
I am learning DOS, (Very painful), I have a 1050 disk drive that was given
to me (no documentation). What I want to do is let my 9 year old learn and
enjoy computers, other than river raid, is their any PD software out on the
net that I can start him with and also the DOS I have with the system seems
to be 2.1 (?) and I can't seem to get it to do anything, is their a book I
can buy to get started or should I go out and get a later version of DOS.
Any help you can provide will be greatly appreaciated.

Thank you, in advance,
Ken Trant

When will the 1200 baud modem for the Atari 8 bits be out?
```

26. 800 expansion

Newsgroup: comp.sys.atari.8bit
Date: 1986-12-14 04:23:51 UTC
From: npk@S.CC.PURDUE.EDU
Message-ID: <8612140423.AA02445@s.cc.purdue.edu>
Source record: 118030

I am expanding the RAM on my Atari 800, I've got more-or-less
complete access to the system bus, and I can deactivate everything but the
GTIA and Antic chips. I am confident that I can add memory just about
anywhere I want to, but I don't know what the conventions are for calling
banks up on the various expansion schemes. The 800XL does one thing, the
800XE does another, and the Axlon Ramdisk boards do something completely
different. The best option seems to use many banks, and a hardware (or
software) switch to determine which machine to emulate, and where the
banks and triggers should be. But I can't find the specs. Where can I find
out EXACTLY what addresses are used and such forth for the 800XL, 800XE, 130XE,
65XE, 800 with RAMDISK, etc? I'm about to etch some memory cards, and I want
to do this right the first time.

Also, the Axlon specification is, I think, that banks are selected
by storing a value from 0 to 7 (for a 128K rambank) or 0-15 (for a 256K bank)
in the top portion of $CFxx. As far as I can tell, those lines are not
available outside of the OS card, except by soldering wires, (which I did).
How is everybody doing this? I'm not out to make a profit, I am a hobbyist,
and I am hoping to donate several bare boards to my high school.
Thank you for your help

Message-ID: <869@chinet.UUCP>
Source record: 118031

Just for your info.....

Atari 2600 Programming Notes

The Atari 2600 (old version) is a useful and flexible SBC for general purpose applications. There are 2 old versions of the 2600 game and they differ only in board layout and physical dimensions. The early version (the one I worked with) measures approx. 4" X 6" and has a 6507, 6532, and a TIA chip onboard. The TIA programming notes are not available at this time. The board also has a place on it for a 24 pin chip. I installed a socket in this area for my eprom. I also installed a 7404 inverter for the chip select to the eprom. The memory map is as follows:

6532 --> $0080 - $0F80
Eprom --> $1000 - $1FFF (top of memory)
TIA --> $0000 - $007F

The 6532 is a multi-purpose chip and has 128 bytes of RAM, 2 parallel ports, and an interval timer. The RAM is mapped to the area of $0080 - $00FF. The parallel IO is mapped to $0280 - $0283. Using the same names as Atari did for the 8 bit computers the ports are mapped as follows:

PORTA --> $0280
PACTL --> $0281
PORTB --> $0282
PBCTL --> $0283

Each pin is addressable and can be configured as either input or output. To set up a pin for output write a "1" into the DDIR (Pxctl) and to set up for input write a "0" into the register. The ports differ slightly in output drive capabilities. PORTA is a TTL drive only and PORTB is a push-pull type of output and can drive darlington transistors directly. The current available is 3.0 ma at the pin.

The 6532 also has an interval timer on board. The timer can count from 1 to 255 divider cycles. Yup there is a programmable divider on board the unit. The divider can be preset to divide by 1, 8, 64, or 1024. The input to the divider is the system clock. The reader is recommended to read any data sheet on the 6532 for more details.

You should install a reset switch onboard the unit so that a reset is available should the CPU not 'come up' properly.

The 6507 can address up to 8 k only, therefore program size is
a limitation. Program code cannot be greater that 4 k in size. This
is usually sufficiant for most general purpose applications. The CPU
clock is derived from the TIA. The TIA divides the crystal clock
(3.58 Mhz) by three to obtain 1.19 Mhz for use by the CPU. Not exactly
real high speed, but sufficient for most uses. I have used the 3.58 Mhz
clock and divided it by two with a J-K flip flop and have had no problems.
The advantage of this is that you don't need the TIA chip and the CPU then
runs a little faster (1.79 Mhz instead of 1.19 Mhz).

Programming Caveats
----

1) There is no stack therefore JSR's are not allowed. (the system will crash)

2) You have to provide for your own reset vector. This would be located
at the very top of your EPROM code.

3) You can use a 2716 or a 2732 for your EPROM. I usually use 2716's.

4) Don't forget to CLC, CLV, or CLD before you start your actual program.
These may be unnecessary for some applications but I leave nothing to
chance. Remember: The generation of random numbers is too important
to be left to chance!

5) There is no IRQ available on the CPU therefore IRQ handling is non-
existent.

The ideal development sytem for this is an Atari 8 bit computer
running MAC-65. The normal system equates could be used and when it is
time to actually put the program into EPROM, you would .include the 2600
equates instead of your computer equates. Don't forget to .set your
offset so that the code can be used by your PROM programmer.

Bit Wise Memory Map

```
------------------------------CPU addresses---------------------------------

6507 --> | 12 | 11 | 10 | 09 | 08 | 07 | 06 | 05 | 04 | 03 | 02 | 01 | 00 |
-------------------------------------------------------------------------------
6532 | cs0 | | | rs | |CS1 | | | | | | | |
-------------------------------------------------------------------------------
EPROM | CS | | | | | | | | | | | | |
-------------------------------------------------------------------------------
TIA | cs0 | | | | |cs3 | | | | | | |
-------------------------------------------------------------------------------
```

* lower case indicates active low.
** rs is ram select line

More Hacks

You could remove the TIA chip and replace it with another chip of
your choice. You will then have to provide a divide by 3 or a divide by
two circuit for the CPU clock. I have done this and replaced the TIA with
a J-K flip flop in a divide by two configuration and have had no problems.
This eliminates the need for the TIA and speeds up the processor due to
the increased clock speed (1.79 Mhz vs. 1.19 Mhz). Most of the chips
shipped with the 2600 should handle this increased speed. I got my board
from Best Electronics in California. A set of prints for the 2600 come in
very handy when configuring (hacking) the system.

The DTI board can also be disabled. But you have to load a short program to do it. (I think the HAPPY is the same way) I have decided to keep my setup completely 'turnkey' so my kids can use it to. Therefore no special software to configure anything.

Correct me if I'm wrong, But you still need the warp speed handlers in the machine for Happy. My suggestion for the OS mod allows any DOS to be used, not just Sparta Dos, to get warp speed.

So even for the Happy system you either have the warp speed handlers in the DOS or in the OS roms. Since I like MYDOS, I chose the OS rom mod route.

All 8-bitters

I think its time for atari to listen to us. Ok the
ST is a great machine and i intend on getting one in the
near future, but the 8-bit still has a lot of untapped pontential.
I glad to see ATARI acknowledge this by working on a 3.5" disk
drive and the xep80 80 col. device. Hopefully this will be
enough to keep the 8-bits alive.

More could be done to rejuevenate interest in the 8-bits.
The Atari OS and the FLOATING POINT routines should be
redone wether or not they enhance the hardware.
A direction i would like to see atari go in would be to
enhance the custom chip set. I see no reason why ATARI
can't add blitting ability to the ANTIC. The antic and
the gtia could be redesigned to add the graphics mode
the xep80 is going to add. Maybe add a 320x400 or 320x200
4,8 or 16 color mode. Also they could speed up the Antic's
data transfer rate. What else could the 8-bit use to make
stand up to its new competion(CoCo III and the Apple][Gs)
And probably tighten the noose around the 128 and c-64?
Well back in 1984? atari showed off a sound chip the Amy or
Amii (which is similiar to the Amiga's?Neil) that would help.
If atari is not willing to do something 8-bits may cease
to be productive machines.

Most of the enhancement could be done without raising the price
more than $100 above the current price of the xe.

Now this new machine seems like it would be in direct competition
with the ST, not really. The ST is still 4 times faster than
the 8-bits. And the ST seems to be heading toward the High business
end of the market(esp if the TT is released)and into the Music
area ,thanks to the insight to include a midi port. Actually this
new machine could help to consolidate the atari line of machines,if
a window type of environment is added to the OS or its DOS.

If any one else has ideas on improving the 8-bit post them
E-mail or mail them to Atari or develope them yourself.

Neil Harris could relay any of the useful information on
to where it has to go.

Hello,
Alright, the 8 bit ATARI world
is getting a little stale isn't it?
What are we going to do about it?
There aren't enough new software
releases to keep everyone excited.
Most ATARI users are probably using
there machines mostly as terminals.
What does the 8 bit ATARI world need?
Two things. First, more ATARI users
must become programmers instead of
videogame couch potatoes. Second, we
must let our voices be heard all the
way back to ATARI. We want a updated
8 bit design! Lets redesign the 8 bit
machine the way APPLE did the][GS
except lets do it for less money. We
would want the 65816 processsor from
Western Digital. New, yet compatible
versions of ANTIC, GTIA, POKEY, and
FREDDIE the custom chips in the
ATARI. If ATARI is too busy with 16
and 32 bit designs to do it
themselves then hire Jay Miner again
as a sub-contractor to do the
design. A renewed interest in writing
software, combined with a more
powerful machine would bring back the
excitment.

Source record: 118034

Is anyone else out there running OmniCom with a P:R connection and an Avatex 1200 modem? I'm having trouble uploading files with Kermit. After I give the file name to send, OmniCom gives the standard
press START/SELECT/OPTION to abort
message, and then, instead of the normal 'blip' of an SIO transfer, I get a rush of static. Perhaps OmniCom has the modem open for concurrent I/O while reading the disk drive?

Download is no problem, and OmniCom is a terrific program, so I wonder if maybe the problem is hardware.

Source record: 118035

Here is the program to create a double-density ATARI DOS 2.0. Presently, it requires two drives only because it was easier to program. The basic idea is to set the appropriate entry in DRVTBL which starts at 4881 and continues for up to 8 drvies. A value of 1 indicates a single density (810) drive and a value of 2 indicates a double density (815, remember them?) drive. Then it does a JSR to DINT to re-initalize DOS and cause it to re-build all tables for disk i/o. Next, an XIO command is used to format the drive (in the command block rcvd by the drive is a flag indicating density) and a trick is used to cause DOS.SYS to be written. Trick= WHENEVER DOS receives a write command and the file name specified is "DOS.SYS", a full copy of DOS is written to the disk with the appropriate updating of sectors 1-4 (which are still written with only 128 bytes of valid data, although in a 256 byte sector). Finally, the slow method of getting and putting is used to transfer a copy of DUP.SYS. If you have only one drive this could be modified BUT a LOT of disk swapping will be needed with the appropriate JSRs to DINT and changes to 488X.

Good luck, if this doesn't make it, let me know.

```

Source record: 118037

Scott:

One person who knows how the memory upgrades work for both the XL and the 800 is David Young, owner of CDY Consulting, Inc.

The Newell board and the 130XE both use $D301 to control bank switching. This is the PIA which controls Joystick ports 3 and 4 on the 800, so I don't think you will want to use this convention on an 800 and lose (?) the free use of the extra joystick ports.

Probably the 800 has to follow the same convention as the XL/XE machines: the extra memory appears in the address space 16K to 32K to avoid upsetting O/S functions and screen handling. However, David Young can tell you for sure, and in fact can probably help you with RAMdisk handlers if you buy his OMNIVIEW 80-column upgrade product. I think on the 800 you end up getting his OMNIMON resident monitor/debugger as a freebie if you buy OMNIVIEW. If so, this is one of those times when it is just plain foolish to resist temptation!!!

CDY can be reached at (214) 235-2146 or by mail at 421 Hanbee, Richardson TX 75080.

****

For those of you who like to see the punch line before you start:

DO NOT, UNDER ANY CIRCUMSTANCES, PURCHASE ANY PIECE OF SOFTWARE
OR HARDWARE FROM HIPPOPOTAMUS SOFTWARE OF LOS GATOS, CA.

Now for the reasons why:

On August 1, this year, I was foolish enough to purchase an EPROM
programmer from Hippopotamus Software from a very reputable mail order
company. After receiving it a week later, I discovered that the only
operation that this programmer could do was to verify that EPROMS were
erased (really functional, huh :-( ). So, I called up Hippopotamus and
asked what the policy was. They indicated that they had discovered some
hardware and software problems with the programmer recently, and asked if
I would send both back to them for repair. So I did.

After about 5 weeks of waiting for some response, I called Hippo
again. They indicated that my unit would be shipped "next week" (computer
weeks, of course). After 3 more weeks, I finally received a new programmer.
Again, I tried to program some EPROMS, with the very same results!!!

Well, now I was furious! Another call, and their secretary answered,
claimed ignorance as to what I was talking about, and referred me to the
product's developer, Rick Oliver. She indicated that he would not be in
until later in the week, and I could call him then. I did get in touch with
Rick later in the week, and he indicated that they had found "yet another
hardware/software" problem, and that I should send the unit back to him again.

Well, call me a fool, I sent it back to them again. And I am waiting
again. So after a few more weeks, I called to see what the #$%^ is going on.
The phone rings about 20 times, and I finally get ahold of an answering service.
They politely talk my message, and indicate that I should receive a call the
next day. Well, I didn't. Another call Monday, a lot more persistent with a
threat of legal action, again no call. Today I called, and the answering
service has been transformed into a mechanical answering machine that
indicates that your message will be delivered in one day (sure, and I was
born yesterday).

I think that you could probably read between the lines and suspect
that Hippopotamus Software is out of business (or showing really bad signs
of being there soon). My advice is to not purchase ANY of their products,
PERIOD. If they owe you money or product, it may already be too late.

I don't really know what my options are now, and would appreciate any
help that those of you in Netland might provide. I feel a lot better just
getting this off my chest, and if it helps even one person out there, I will
consider this a success.

Myron Drapal

Bill:

You should consider buying CDY's OMNIMON debugger. It lives in ROM so is always available, even when a program just crashed so badly that other debuggers are out of luck. Having to re-boot often loses vital information like where your program was when it crashed. With OMNIMON you can press a few keys and see what was in the program counter at the time of the crash, or whatever else you care to know. It's not public domain, but it will do all of what you are asking for and then some. In particular, it will read sectors, disassemble them, let you patch them and write them back.
Even neater, it gives you the choice of reading successive sectors sequentially or hopping from sector to sector according to the link bytes. And it knows how to read and display the file directory of a disk even if there is no DOS on the disk or loaded into the machine! If you are at the point where you want to edit disk sectors, you CERTAINLY ought to install OMNIMON in your machine.

The only other thing I know of that even comes close is OSS's BUG65 which comes with MAC65. But it has to be loaded, so can't be used unless you knew you were going to need it. It DOES do sector reads and writes so could do what you were asking about.

I think I have a PD debugger of some sort at home, so will look for it tonight.

41. Action! source code for Kermit & Keyboard Controllers

Newsgroup: comp.sys.atari.8bit
Date: 1986-12-17 15:07:42 UTC
From: daroloson@watmath.UUCP
Message-ID: <3983@watmath.UUCP>
Source record: 118045

Does anyone have a copy of the Action! source code for
Kermit that they would be willing to mail me?
Any Action! programs/programming hints would also be appreciated.

Also the 2600 has two different keyboard controllers, each
with 3 columns and 4 rows of buttons.
One with rounded keys that is used for Basic Programming,
Concentration and Brain Games and another one with a plastic
overlay used with Star Raiders.
How does one read these on the 8-bits, I have tried the
joystick registers but several keys give the same result.

Thanks,
Dani Roloson

42. OmniCom Kermit Troubles

Newsgroup: comp.sys.atari.8bit
Date: 1986-12-17 18:30:41 UTC
From: hyc@UMIX.CC.UMICH.EDU
Message-ID: <8612171830.AA20961@umix.cc.umich.edu>
Source record: 118046

Summary of problem - with OmniView, OmniCom, and P:R Connection running with the "standard" RS232 device handler, Kermit uploads hang OmniCom.

Mediocre solution - use PRC.SYS instead of the 850 RS232 handler.

Gripes - the 850 RS232 handler signals when its buffer overflows, allowing OmniCom to send an XOFF until it catches up. The PRC.SYS does not. This is usually not a problem, but I also run OmniCom over a 9600 baud line, and it becomes pretty important then. The display seems to max out at about 2700 baud, so buffer overflows mean garbled text. With the 850 handler, the XOFF takes care of things just fine. With PRC.SYS, I get a mess. And, of course, with the 850 handler, I can only receive files, whereas the PRC.SYS will allow both sending and receiving with no problem. This seems to only be a problem with OmniCom and the 850 handler, I don't recall it happening with the PD Kermit.

I'm curious, Dave, what is it about OmniCom that makes it so incompatible with the P:R Connection? The initial version wouldn't work at all without PRC.SYS, while the version I got recently works "most of the time..." (I'm also curious as to what you used to write it; the load vectors for that thing are horribly inefficient!)

43. Re: OmniCom Kermit Troubles

Newsgroup: comp.sys.atari.8bit
Date: 1986-12-18 12:42:07 UTC
From: DYOUNG@A.ISI.EDU
Message-ID: <8612181248.AA03534@ucbvax.Berkeley.EDU>
Source record: 118047

I have no idea what the problem is with the P:R connection and the
850 handler. If I knew and thought I could compensate for it in OmniCom
I would. The thing is evidently not completely 850 compatible as their ads
claim. I would contact the manufacturers and complain.

I use the Atari Macro Assembler which generates those inefficient load
vectors. With a little effort you should be able to convert the file
to one continuous load. Since I always run it out of a ramdisk I
never notice.

44. Re: Action! source code for Kermit & Keyboard Controllers

Newsgroup: comp.sys.atari.8bit
Date: 1986-12-18 15:28:26 UTC
From: appelbau@topaz.RUTGERS.EDU
Message-ID: <7971@topaz.RUTGERS.EDU>
Source record: 118048

In article <3983@watmath.UUCP>, daroloson@watmath.UUCP (Dani A. Roloson) writes:
> Does anyone have a copy of the Action! source code for
> Kermit that they would be willing to mail me?

My next posting will be the complete KERMIT sources in ACTIO!. This
includes modules for the 850 interface, as well as the 1030 modem.

In article <1524@druhi.UUCP> med@druhi.UUCP (DrapalME) writes:
> On August 1, this year, I was foolish enough to purchase an EPROM
> programmer from Hippopotamus Software from a very reputable mail order
> company.
[he goes on to describe problems with the EPROM programmer, and problems
with trying to get Hippo to fix it]

If it was a "very reputable" mail order place, then you should be able
to send the EPROM programmer back to them, explaining that it doesn't
work, and they should then deal with Hippo.

++++++++++++++ HELP +++++++++++++++

I have written a program for the Atari in Action, and I am Having trouble
with the RS232 ports. If anyone has an idea on what is going on PLEASE
respond, before I pull ALL of my hair out!!!

This program is for use with the X10 POWERHOUSE interface. If I ever get it
fixed I will post it here.

My problem.

I have a routine that opens the R2: port and starts concurrent mode operation.
It sends the info to the X10 and waits for a reply by using XIO 13 to get
the status of the input buffer. It gets the input, closes the port and
and returns to the calling procedure.

BUT this usually only works the first time I call it. The second time I call
it I get error 132 (illegal XIO command - the concurrent mode-) or
error 154 (attempt to input from a R: port without concurrent mode active).
I am using the standard 850 handler for all of this. I have tried moving the
location of this procedure around in memory and the results are the same, so
I don't think I have a 'lost' pointer in my program.
This problem isn't there all the time. If fact I have compiled withe the
run time lib and when I run the result over and over, sometimes it works fine
and sometimes (usually) it bombs. The procedure allways works once, and if
it works twice it seems to work forever. Sometimes I can get a compile to
work by having a file in the edit buffer at compile time, this indicates
a code location problem. But the size of the file in the edit buffer is
important, sometimes the one I picked last time won't work this time.

I realize this sounds like a lot of bable, but after many late nites fighting
this mess, this is the best I can do. (:>

Any pointers to what simple thing I am overlooking whould keep me
forever in your debt.

Ted O. Burger

48. Re: questions

Newsgroup: comp.sys.atari.8bit
Date: 1986-12-19 16:31:33 UTC
From: sharakan@godot.think.com
Message-ID: <392@think.COM>
Source record: 118052

I tried creating a double-density DOS2.0 using the program posted and had no luck. I have a 800XL with a 1050 drive w/U.S. Doubler installed. I made the following changes to the program to allow it to work with one drive:

```
840 POKE 4881,DOUBLE:X=USR(ADR(DINT$))
^
880 XIO 254,#1,0,0,"D1:*.*"
^^^ ^
980 OPEN #2,WRT,0,"D1:DOS.SYS"
^
990 CLOSE #2:END
^^^^
```

(The '#1' in line 880 is necessary Atari BASIC syntax). These changes should have created a double density disk with a DOS.SYS on it. Rather than using gets/puts to copy DUP.SYS, I simply went to DOS and used the 'O' option to copy it over. (I don't know if I would have been able to do this if the program actually worked).

What I got was a single density disk with a DOS that still did not support double density. The U.S Doubler in my 1050 is supposedly compatible with other double density drives on the market.

Any help from the Net would be most appreciated. Thanks in advance.

49. XL/XE Used as VCR Titlers

Newsgroup: comp.sys.atari.8bit
Date: 1986-12-19 21:50:44 UTC
From: wrd@tekigm2.UUCP
Message-ID: <1320@tekigm2.UUCP>
Source record: 118053

Some time ago, there was an article in either ANTIC or A.N.A.L.O.G. magazines that told how to use an Atari 800/XL/XE as a source of titles for VCR tapes. I have tried to connect my computer and VCR together to do this and cannot seem to find the proper connection scheme. Does anyone either remember which issue of which magazine that this appeared in or does anyone know how to do this?

I have tried connecting computer to switchbox on games with VCR without success, similarly have tried inputing computer to VCR signal in RCA jack, but again no success. I have VCR set up to use ch 4 and computer to use ch 3, figuring that I could then set VCR to channel 3 and receive the signal from the computer, but again no success. I only seem to be able to use the VCR or the computer, but not both together. (Both work fine by themselves with no changes in wiring and with the other device shutoff.)

Thanks in advance

> double density. The U.S Doubler in my 1050 is supposedly compatible with
> other double density drives on the market.
>
> Any help from the Net would be most appreciated. Thanks in advance.

I was able to get the program posted to work by making a few changes.

1)Format the disk to be used in double density ahead of time using
Spartados, SmartDos, or whatever you may have. *Remove* the XIO
statement from the posted program.
2)If you use an xl/xe (like me), boot up using a "translator" disk.

This will give you a *mostly* working copy of double density Atari
Dos 2.0. I say mostly because for some reason, the copy I end up
with *will not* format a disk - which means I have to use SmartDos
or whatever for that purpose (anybody out there have a solution
for that problem?).

52. New 8 bit design

Newsgroup: comp.sys.atari.8bit
Date: 1986-12-22 05:27:40 UTC
From: conklin@cps.mich-state.CSNET
Message-ID: <8612232021.AA28313@ucbvax.Berkeley.EDU>
Source record: 117956

Ok, now it seems I'm not the only one who would like to see the 8 bit architecture taken farther. Many different proposals have been forwarded and not always just as wishful thinking, but clearly defined upgrade paths. Is Atari listening? It's difficult to tell. The XM301 was certainly what we had in mind. But skimping on the second IO connector wasn't on the order. The new 1200, if it really has both RS232 and SIO ports, is a -lovely- piece of hardware (you can bet I'll have one!) But what, besides a basically incompatible 80-column board is in mind for the 8 bits? Does anyone record, or even consider the extention's proposed?

Because, in the nature of profitable business, the only proposals Atari will probably consider are clearly profitable (that is, not make money, make a lot of...) I would like to submit yet one more option for Atari to consider in the interests of expanding the 8 bit line.

Have Atari ever considered releasing the designs of the Atari custom chips to the public domain under an "open systems" attitude along the lines of Sun?

Obviously, chip designs are -not- generally on the bill of things attributed to an "open architecture" approach, but the 8 bit design is so locked into those chips that they are really the last, and biggest, part of the machine left untouched. Atari will always be the "real" manufacturer of the 8 bit, but tossing GTIA and ANTIC to the world would allow for the one thing that has never been tried on the Atari. (And you thought everything had been done..) Hacking the logic. No, it's not for home computist, but then again, when Atari releaed the OS source and hardware descriptions with the machine long ago, they were way over the head of the general public.

And too, you can gaurentee they'll be hacked. At one point, the design of ANTIC was a mysterious beast, a rare feat of it's time. Today, just here at MSU, that level of chip design is almost completely supported by the VLSI tools. I'm not even sure ANTIC counts as anything more than LSI! If no one at all was capable of modifying (and test/producing an ANTIC+ or whatever) at the most it would cost Atari nothing. At best, some enterprising CE might release their extention back to Atari, or sell it to a third party for production. In fact, if ANTIC, GTIA and POKEY were to become public domain, technically it would be possible to build an Atari-compatible. Don't laugh. There were TRS Model I compatibles at one point. And as IBM has proved beyond imagination, clones increase the originals business.

This kind of option, clearly, would only be taken by a company tha opens new doors. But I wouldn't have mentioned it if I didn't think Atari of being capable of that kind of ground-breaking. Every time I see an ST, I'm sure of it.

53. monitors for the 800

Newsgroup: comp.sys.atari.8bit
Date: 1986-12-22 20:37:26 UTC
From: rgenter@J.BBN.COM
Message-ID: <8612222050.AA12494@ucbvax.Berkeley.EDU>
Source record: 117957

As has been mentioned several times, it is recommended that a video monitor be used with your Atari 800 if you are going to use Omniview (CDY Consulting's 80-column ROM). I am currently using Omniview with my color TV, and though it is working remarkably well (I still don't understand how the characters can be so legible at only 4 dots across), I would like to get better screen definition and readability. Does anyone have a specific brand of monitor they would like to recommend? Also, if someone would repost how to get the appropriate video signal out of the 800 for use with such a monitor, I would be grateful. (Note I am talking 800, *NOT* 800XL.)

By the way, noone has responded to my request regarding the pin-out on the 850 serial ports yet. If anyone has that knowledge available I'd love to hear from you.

57. RAM upgrade

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-03 20:34:20 UTC
From: wilmott@topaz.RUTGERS.EDU
Message-ID: <8183@topaz.RUTGERS.EDU>
Source record: 117961

.

I'm going to be upgrading my 800XL to 256K this month, but am
undecided as to which upgrade to go with. The RamboXL from ICD
sells for $29 mail order, but does not include the RAM chips.
The Newell 256KXL from Newell Industries sells for $55
mail order. Anybody have any comments (pros/cons) about either?
Is one easier to install than the other? Is one more "XE
compatible" than the other? And, *most* importantly, which
works out to be cheaper? (ie- how much does a set of RAM
chips (I believe 8 256k 150ns DRAMS) go for these days?)
Any info greatly appreciated.

-Ray

FEBRUARY 1987 ANTIC TOC
Theme: Word Processing

page article

8 I/O BOARD
Letters from Readers.
10 GAME OF THE MONTH: QUATRO
A colorful computerized version of Blind Man's Morris, the
traditional strategy game where you beat an opponent by
lining up four pieces in any direction. Compete against your
Atari or a human opponent. BASIC.
16 HOW TO WRITE BOOKS WITH YOUR ATARI
A simple 'how to' write a novel using your Atari and a Word
Processor by David Wade who has written 15 novels under his
own and other names. (He uses an Atari 130XE and PaperClip).
20 SAN FRANCISCO FOGGER
A program that checks your letters, reports and term papers
for readability. It gives a Fog, Smog and Flesch Index
output. Both 8-bit and ST programs are provided. BASIC.
24 WORD PROCESSORS: 7 FOR THE 8-BIT
A review of 7 word processors available for the 8-bit Atari's.
It includes a nice table of all important features and which
Word Processors have what.
31 NEW PRODUCTS
A description but not a review of several new products
available for the Atari computers.
34 130XE DOUBLE FEATURE
An article detailing the difficulty of using the extra
64K of memory from within a BASIC program.
35 RAM BANKS ON THE 130XE
An article by Bill Wilkinson (of OSS) detailing the how to
access the full 128K of memory, especially if you want to
use OSS's BASIC XE.
38 130XE SLIDE SHOW
This short program demonstrates how you can use Atari BASIC
to control RAM bank switching. It allows you to store 8
graphic pictures in the extra memory and flash them at a
rate you control using Atari paddle controllers.
42 ELECTRIC CHARLIE
A program that uses pop-up windows to explain error message
numbers returned by main program.
44 REBOUND CONSTRUCTION KIT
```

A construction kit (and contest) to allow you to produce
extra screens to go with the game 'Flip Ogart' from last
months ANTIC.
47 PRODUCT REVIEWS
Software
Millionaire (Blue Chip Software)
Super ReeveKey (Reeve Software)
Top Gunner (MicroProse Software)
World Karate Championship (Epyx Inc.)
Hardware
Dots-Perfect Upgrade Kit (Dresselhaus Computer Products)
-an upgrade for Epson FX, JX, RX, and MX printers
52 COMMUNICATIONS: ATARI'S BULLETIN BOARD
An article on Atari's own BBS. They are now running 5 ST's
with hard disks and logging 12,000 calls a month. The five
run duplicate but separate data bases. The five telephone
numbers are (408)-745-5308, -5970, -2642, -4758 & -5664.
55 NEW OWNERS COLUMN
This is lesson 11 on ATASCII, PEEK and POKE commands and what
they do and how to use them.
60 USERS GROUP: WAACE
The featured users group this month is the Washington Area
Atari Computer Enthusiasts. This isn't a users group, per
se, but an organization that exists to coordinate the efforts
of all the users groups in the DC area. It also publishes
the user group magazine 'Current Notes' that is highly
respected thanks to Joe Waters. If I had to choose between
it and ANTIC, I'd drop my ANTIC subscription first!

61. 8 bit languages

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-06 04:30:53 UTC
From: dlm@ho3cad.UUCP
Message-ID: <551@ho3cad.UUCP>
Source record: 117965

Looking for a reasonable language for your 8 bit atari? Grossed out by BASIC?
I have been using ACTION! from OSS for software development lately. It has
been an outstanding language development environment.

My previous ATARI language experience has been BASIC, ATARI assembler,
ValFORTH, Deep Blue C, and now ACTION!. ACTION! is by far and away the best
ATARI development environment.

BASIC and assembler need no words. Avoid at all costs.

ValFORTH was an interesting system. Although I would not use it for any real
project, it was a fascinating journey into threaded interpretive languages and
a good learning experience in the style of FORTH. Since the interpreter,
compiler, and your program live in the same run time environment, you can
modify the behavior of the compiler as your program is compiled into the
pseudo-machine language. However, it suffered from:
- It really wasn't as compact as is made out by FORTH enthusiasts. I
was left with little space after loading alot of useful packages
- FORTH is truly hard to read. Western Human math just doesn't word
in reverse polish notation.
- It is difficult to document. The commentary system takes up too
much valuable area in each `screen'
- It is totally incompatible with all other 8 bit software. It cannot
generate programs that can be placed on any DOS file system. I
acquired a DOS like package for FORTH, but it took up much more
space then DOS 2.5 and DUP, leaving very little main memory
- debugging facilities were terrible. Since the compiler and run time
environment co-existed, almost any bug caused the system to hang.
Too bad you forgot to save some `screens' to disk :-)

Deep Blue C was an attempt to get a real compiler/linker. It's not bad as
they go, but it turns out that the 6502 is just too primitive to compile C
for. So this compiler actually turns out a sort of p-code anyway, hence once
again, we do not have a language that can rival assembler code. Also, once
again, debugging facilities are non-existent. Turn around on compiles are
very slow. Until I got a 130XE with a ram disk to hold everything, this system
was impossible to use. In addition, Deep Blue C did not do:
structs
functions returning anything but int
strings cannot continue on the next line
source lines must be less than 79 chars
pointers to pointers

After all of this, and refusing to use a macro assembler, I went for ACTION!
ACTION! is easy to use since it is very C and PASCAL like. The manual is 208
pages long and is very complete. ACTION! has an editor, compiler, monitor, and

run time library in an 8K cartridge form (not really 8K, since it bank switches
but it does only use 8K from your RAM address space). Being in a cartridge, it
is almost (but not totally) crash resistant. Reset almost always gets you back
to the editor. The editor and compiler work together. The compiler stops on
any error, but the editor/compiler loop is so fast that this is actually
more effective than a fancy compiler that continued to give error messages.

All the language constructs are there that I feel I really need. For example:
structs
arrays
pointers (to pointers ...)
address of (including address of functions)
full complement of arithmetic, logical operations
full complement of assignment, including C like =+ =- =*, etc
defines
16 bit signed, unsigned, 8bit unsigned
if/then/else/elseif
do while until for and an exit (loop) construct
functions and procs
generates executables in DOS loadable format
(takes a special package to allow an executable to exist
without the cartridge, but it is possible)
In fact, ACTION! exists TOTALLY within the standard ATARI operating environment.

I have a program that is 5 pages long (~20 commentary) that compiles in
seconds (from the editor buffer). Of course compile time from disk will be
dominated by disk i/o speed. Compile from ram disk is almost indistinguishable
from compile from editor buffer.

Hope some of you find this collection of personal opinion useful.

62. Chameleon help request

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-06 12:21:50 UTC
From: crd9852@ritcv.UUCP
Message-ID: <395@ritcv.UUCP>
Source record: 117966

A friend of mine let me borrow his 1030 modem for a while. He bought an ST and has another modem to use with it. He also let me borrow his copy of Chameleon. There seems to be a few bugs with the VT52 emulation.

Maybe someone out there can help me. I have Chameleon version 4.03.
The termcap file that came with it is for a terminal similar to a VT52. It really does not seem to work. For example, according to the temcap file, the code for a clear screen is Escape H Escape J. That does not work. Yes, I did set up Chameleon to emulate a VT52XL and executed the termcap file I downloaded from the Chameleon disk just like the instructions said.

Does anyone know of this problem and possibly any soultions to what I've mentioned? Oh yes, something else I noticed. When Chameleon is set up to emulate the Glasstty and I am listing something to the screen and I fill up one line, the next character to
print wraps around to the next line just like I would expect. However, when I am in either of the VT52 modes, it does not wrap. The excess characters just overwrite one another in the last column on the screen. Is this a known problem or is it perhaps a switch in the termcap file?

Thanks for any help. If I can get this working, maybe I can use vi from home. Of course, any problems I am having could be due to operator error and not bugs in the software!. In case it matters, I am using this on an 8000XL. Just in case you are wondering and to prevent any flames, I am waiting for the Atari 1200 baud modem to hit the market. I will return the modem *and* software to my friend. I am not and have no intention of pirating this software.

63. Atari Artist & Movie Maker file formats wanted

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-06 17:13:10 UTC
From: jwn@cbuxb.UUCP
Message-ID: <351@cbuxb.UUCP>

I'm submitting this again because the address may not have
been enough to get a reply back to me.

I want to use Atari Artist to draw pictures to use in
Movie Maker since Artist uses a tablet vs MMs joysticks.
To do this I need the save file formats for Atari Artist
and the background and character files for Movie Maker.

I'm modestly impressed with what Movie Maker can get out
of the 8 bitter, but changing disks and joystick drawing
are a pain.

Atari Artist does compression of the picture.

Anyone interested in this should go out and buy a copy of the January issue of ANALOG magazine (#50). THe article on page 33 described just what you need.

I am putting the finishing touchs on an ACTION! program to dump Atari Artist/ Micro-Illustrator files to an Epson printer. I'll post it if there is anyone interested.

Someone expressed interest about having trouble with Chameleon.
I have a vt52 emulator that I wrote called vterm. It works on all computers
and 850/smartmodem and 1030 modems.
I mentioned this a while ago, but never got around to posting it.
The reason I didn't was because I didn't know the correct procedure for
encoding and posting a binary file to the net.
If someone can send tell me how to do this (and send me the little basic
program to do it maybe) I will be glad to post it.
It works just beautifully with vi.
I have no trouble on sally with vt52 emulation.
Perhaps I can include the termcap here also.
It is similar to Chameleon in that it has a scrolling 80 columns.
The rest of it is somewhat different.

It is a VERY good vt52 terminal emulator.

67. Chroma/Luma on 800XL

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-07 15:16:22 UTC
From: fisher@star.dec.com
Message-ID: <7398@decwrl.DEC.COM>
Source record: 117971

A raging (well mild) debate has been going on around here regarding the presence or absence of a chroma signal on the 800XL video output. Could someone give a reasonably technical explanation of what the situation is?

Synopsis of the argument:

An article a few years ago in Antic says that XLs don't have chroma. However, it appears that when you hook up the luma/chroma output pins to the luma/chroma inputs of a monitor, it works. There is some confirmation for the Antic side if you look at the board. There are four connections to the video jack. This is just right for Composite/Luma/Audio/Ground; no room for a chroma signal.

There are also references floating around to the fact that it is possible to get the chroma signal with a magic capacitor or two, but nothing definitive has surfaced.

Questions:

1. Is it true that there is no chroma on an 800XL?

2. If so, what IS happening when we make connections to the chroma input? (For example, does composite into the chroma input have the same effect?)

3. Can we get chroma via hacking?

4. Does it matter?

Thanks.

Burns

RE: Chrominance output on XL

I don't know why you think that the video output on the 800XL only has 4 pins... I have a 1200XL which has the same connector, a DIN 5 pin jack.

Anyways, yes, it IS true that there is no CHROMINANCE (chroma) available on the XL's, and it is also true that it is possible to add it.
I added it on my computer with a simple wire off of a resistor going to the video modulator. As the chrominance is required to modulate color so that you can hook up a tv to the rca jack. You can tap this signal without any problems using a 220 ohm resistor soldered to one end of a resistor going to the modulator. I don't remember the number on the board, and I am sure the numbers would differ for the 800, so you'd have to check schematics for your computer.

Nick

Joe -

The following messages contain descriptive text and sources for a couple of little dogs I wrote in Atari Basic called BINHEX and HEXBIN. They convert public domain binaries to HEX text, for sending across the net in text messages, to be converted back to Binary again on the Atari at the other end. A simple check-sum scheme is used to ensure nothing has been dropped in transmission. A few binaries have been circulated in the past couple of years using BINHEX and HEXBIN. They run pretty slow, but mailing a floppy across the country isn't exactly free...

Everyone else -

Message me if you don't have these files and want them.

Dan

71. Information on BINHEX???

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-08 03:00:26 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8701080300.AA28134@mitre-bedford.ARPA>
Source record: 117975

Does anybody have a precise definition of the output format of BINHEX?
I would like to convert my uudecode routine to decode BINHEX files, but I
am not sure of some of the details. Specifically...

In the one example I have (TURBO BASIC), the file begins with the line
".START.<RETURN>". Then there are many lines of precisely 36 Hex digits,
followed by a <RETURN> after each such group of 36. Finally there is a line
with only 28 Hex digits, followed by a <RETURN>. Well, not really finally,
because there is another line with ".STOP.2397155<RETURN>" followed by a
line with four special graphics characters and a <RETURN>. It looks as if
the special character may be Hex $01, repeated 4 times.

I suspect that the "2397155" may actually be the decimal value of the sum of
the bytes in the file. This would be about right if the data values are
biased toward being between 0 and 127. The file contains about 36K bytes, by
the way.

I am not sure of several things, and would like answers to the following
questions from someone who is sure of the answers:

1. Is there some internal coding of the length of each line, as in uuencode?
If not, how is the decoding program supposed to know when it has encountered
the last line? Must it simply look for the .STOP. line?

2. Is the data following .STOP. indeed a checksum? If so, is it just what I
said I suspected, the decimal sum of the bytes? Or what?

3. What is the purpose of the four $01 characters at the end? A marker of
some kind or just some junk that got included somewhere along the way?

Any help that is forthcoming will be appreciated. If anybody wants the
HEXBIN subroutine when it is finished, or the main program that will use it
to decode files, send me a note to that effect and I will post the program.
Please, however, allow several weeks for delivery, based on my recent
performance in getting programs "out the door".

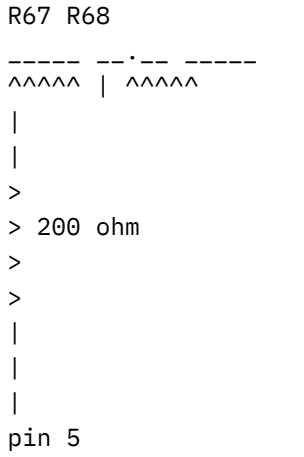
73. Chroma on 800XL

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-08 15:32:20 UTC
From: wrd@tekigm2.UUCP
Message-ID: <1355@tekigm2.UUCP>
Source record: 117977

The attached is a slightly modifed version of an article I sent out on the net some time ago.

Subject: XL/XE Monitor Output Jack Mods, Etc.

Here is the solution for the lack of chroma in the 800XL that was published in the February ANTIC i/o board column? Essentially it says that the chroma output is at the emitter of Q5. You need to connect a 200 ohm resistor from the junction of R67 and R68 to pin 5 on the monitor connection. Credit for this goes to the Chicagoland Atari Users Group. Two questions: is the 200 ohm value correct (recently someone mentioned 220 ohms) and what is the proper value/connection point for the 1200XL which has a similar problem. In fact the 1200XL will not give color if connected to a separated video monitor in the same fashion as an 800XL.



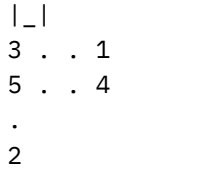
Note: resistors R67 and R68 actually are next to each other and not back to back as this diagram would indicate. I have intalled this on my 800XL and the picture I get on my Commodore 1702 monitor is nearly identical to that from my 130XE. (I would suggest to install this on the bottom side of the board. It is easier to get outside of the shield that way and also it is easier to solder.)

Question: the diagram for the 130XE shows --
pin 1 composite luminance
pin 2 ground
pin 3 audio output
pin 4 composite video
pin 5 composite chroma

-- the 800XL still has one pin not used (I think pin 4), what does this mean? Should this remaining pin be connected? If so, to what?

Then on the 1200XL, I find that pin 5 is not connected to anything, but pin 4 is. Is pin 4 composite video on the 1200XL and if so, should I connect pin 5 to pin 4 or to something else (on the 1200XL) -- see 1200XL question above?

SUBJECT: PIN CONFIGURATON:
By the way the pin configuration (per the 130XE manual, as looking at the connector on the computer is:



This pin numbering scheme is a German VDE standard and is common to all of the Atari 8 bit machines, however, not all utilize or have all five pins wired.

74. Re: Chroma/Luma on 800XL

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-08 19:45:57 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8701081946.AA10965@mitre-bedford.ARPA>
Source record: 117978

1. No, there is no chroma output on the stock 800XL.

2. Yes, it can be brought out, as it is present internally. One group that did this says that a 200-ohm resistor from the junction of R68 and R67 to Pin 5 of monitor jack J2 will do it. On the other hand, this will obviously give a somewhat higher than standard source impedance, which could cause loss of resolution if the other end of the monitor video cable is not properly terminated. You might want to fiddle with the circuit to get the proper source impedance while keeping the proper chroma level. If you need help, I can probably provide it or find someone who can. At most you would need to change the resistor value and perhaps add another resistor to ground or something to get it right.

The source impedance would be approximated closely by 20 ohms plus the series resistance you use (200 ohms in the above example). Most of the 20 ohms comes from the emitter resistance of Q5 which is about 26 ohms at room temperature for most silicon small-signal transistors. R66 shunts this to bring it down to the 20 ohms. R75 should have little effect since nothing will be connected to Pin 4 of J2. To get a 75-ohm source you would therefore need about 56 ohms in series (a standard value) but this would increase the chroma level quite a bit. You should be able to figure out a series/shunt combination that gives 75 ohms (or 50 if that is what your monitor wants) and still gives a reasonable chroma signal level at the monitor.

3. Yes, it does matter. If you use luminance and chroma separately in a NTSC decoder which uses the full chroma bandwidth, you can get resolution essentially as good as the better RGB monitors give. Some monitors such as the Commodore 1802 (?) do this and give excellent results -- more than good enough for 80-column word processing with CDY's OMNIVIEW upgrade chip, for example. Other graphics applications also look much better with the enhanced resolution, I am told. It's a very simple mod -- "go for it"!

I am going to try to kill two birds with one stone with this posting.

Chrominance is available on all Atari 8 bitters. Whether or not it is
wired to the connector is another matter. For the 800XL connect a
220 ohm resistor from the emitter of Q5 to pin 5 of the DIN jack.

On the 1200XL (which is my personal favorite) connect a 220 ohm resistor
from the emitter of Q7 to pin 5 of the DIN jack.

And now for the Joystick pinout.....

Atari Joystick pin-out
(console end)

```
\---------------------------------/
\1 2 3 4 5/
\ /
\ 6 7 8 9 /
\-------------------------/
```

1 Forward
2 Back
3 Left
4 Right
5 Pot B
6 Trigger
7 +5 volts
8 Ground
9 Pot A

Hope this answers all of the questions.......

78. Re: 800, 800XL

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-11 01:44:41 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8701110144.AA15039@mitre-bedford.ARPA>
Source record: 117982

The best source I know of for the differences is Mapping The Atari, 1985 Revised Edition, Appendices 12 - 15, 18, and 19 (and maybe some other places).

Some differences that come to mind are:

1. The 800XL uses a custom 6502 chip with built-in tri-state drivers and a HALT input to make them disconnect the 6502 from the bus so ANTIC can take over. HALT is generated by ANTIC when it needs the bus. The custom chip is the famed "Sally" chip. In the 800, the tri-state function is done with external buffers. This is transparent to software but makes some difference if you want to make hardware modifications. In particular, the 65802 CPU chip from Western Design Center should drop right into an 800, giving a greatly enhanced machine language instruction set, but in the 800XL it would require a piggyback board with 800-style tri-state buffers.

2. The memory map is slightly different. Mapping The Atari details the differences far better than I could do here. One example I have run into is that memory location 731 (decimal) on the 800XL is called NOCLIK; if it holds a nonzero value, the keyboard click is disabled, but if it is zero the click sound is generated for each keystroke. On the 800, location 731 is unassigned and there is no way to turn off the key click.
Some old 800 software will refuse to run on the XL/XE machines unless you first run the Translator Disk. What this does is to switch out the ROM containing the normal XL/XE O/S and load a copy of the old 800 O/S (more or less) into the RAM which normally hides under the ROM. Then you can boot your old software and it will think it is running on an 800.
If you run into this condition often and find it a nuisance to have to run the Translator Disk every time, one solution would be to buy CDY's OMNIVIEW O/S replacement chip. This acts so much like the 800 O/S that most old software will run perfectly without the Translator Disk. OMNIVIEW also gives you an 80-column display capability, improved floating point software that will make your BASIC programs run noticeably faster, and built-in RAMdisk handler (OMNIVIEW256 version) which turns the Newell 256KXL memory expansion board into a RAMdisk that can be used with any version of DOS. Oh yes, and a free 80-column word processor is included as well.

3. The 800XL of course has the parallel bus connector on the back, making it possible to build custom interfaces to the CPU bus. I believe there are 10Mbyte hard disks available that use this point of connection to obtain very high transfer rates.

4. The 800XL has only two joystick ports instead of the four on the old 800. On both machines, a PIA chip (Parallel Interface Adapter) is used to run the joystick ports. Port A runs Joysticks 1 and 2 on both machines. On the 800XL, PIA Port B is used to do some internal switching rather than controlling Joysticks 3 and 4 as it does on the 800. For example, Port B

is used to select O/S ROM or RAM in the upper 16K of memory (Bit 0), BASIC on or off (Bit 1), and diagnostic ROM on/off (Bit 7). Bits 2 through 6 are used for memory bank switching in the 130XE and the Newell 256K memory expansion board mentioned earlier. The PIA Port B is accessed as memory location 54017 (Hex $D301).

That's about all I can think of offhand. Hope I hit the main points you needed to know.

80. 800XL chroma

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-12 02:31:07 UTC
From: fisher@star.dec.com
Message-ID: <7474@decwrl.DEC.COM>
Source record: 117984

Followup: I followed the instructions of several respondants and got a chroma signal from the junction of R68 and R67 and took it to pin 5 through 200 ohms.

I ran the existing lumma signal to the lumma input of my Commodore 1702 monitor and the new chroma signal to the chroma input. Yes, it does work fine. However, I have to say I can't tell the difference between using the new chroma signal composite video into the chroma input. Both seem equally good. I guess I can see now why Atari did not bother with the separate chroma when the designed the XL.

Notice that I am talking about running composite to chroma input. If I run composite into the composite input, the picture quality is distinctly inferior.

Just curious...has anyone else (perhaps someone with an 800 non-XL) tried substituting composite for chroma? Can you see the difference?

Thanks for all your help.

Burns

fisher%star@DEC.COM

81. Re: 800XL chroma

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-12 13:53:05 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8701121353.AA08472@mitre-bedford.ARPA>
Source record: 117985

Looking at the schematic to the 800XL, it appears that the composite video output does not include any filtering to limit the bandwidth of the chroma signal before combining it with the luminance, as is normally done in television broadcasting. This would explain why the composite signal can be used as an input to the Commodore monitor's chroma input without loss of resolution. I am surprised that there is no visible difference, however, because I would think that the luminance signal might cause interference with chroma circuit operation.

RE: REPOSTINGS

Many local Atari fans without access to Usenet would like to see a selection of the postings here. My inquiries have not discovered any claim on these Usenet postings outside the implicit rights of the contributor. Some Usenet contributors have added notices like: "not for circulation outside Usenet"; of course any such wishes would be respected. Does anyone have any comments about selective reposting to a local Atari club BBS?

RE:TURBOBASIC

TURBOBASIC XL is quite a nifty item. It's clearly a "professional" product. The fact it has been placed in the public domain indicates there are clever people out there with a real love for the machine.

Apparently there is also a compiler and runtime package also in the public domain, that is fully compatible with all features of the language; therefore it will also compile any ATARI basic program too. Anybody got any reviews of the compiler? Better yet, can anyone post it to the net?

Atari at CES -- Winter 1987
A sneak preview of what's new.

(Las Vegas -- January 7) -- The motto of Tramiel's Atari Corporation has
just been updated. Instead of "Power Without The Price," Atari's battle cry is
"Where the Action Is."
The action started with three major hardware announcements from Atari.
First is Atari's introduction of the new "Mega" ST series.
Atari has altered their 16-bit product line in both features and styling.
The new STs are component systems, similar in appearance to an IBM PC, but less
"clunky" -- they bear a sleek micro-stereo component look. A detachable
keyboard connects via cable to a separate box housing the CPU, an included
double-density 3 1/2 inch drive and a battery-sustained real-time calendar
clock. Cosmetically, the Mega STs are the same dove-gray ST color, the
separated keyboard resembling a 1040 ST with the diagonal vent area sliced off.
The keyboard, by the way, has a much crisper feel to it than current ST
keyboards, although key layout and the keytops themselves remain unchanged.
The new STs are designed as "open architecture" machines. Expansion
devices such as add-on cards might be plugged into a peripheral box, which would
then connect to the ST through the DMA port or bus expansion connector. In the
future, such a box could feature dedicated chips, such as the new Motorola 68020
and the 68881 math coprocessor, giving blinding speed to graphics processing,
real-time animation and other memory intensive, number-crunching functions. The
Mega STs will be available in 1, 2 and 4 megabyte configurations, with prices
reportedly starting at around $995. And yes, the Mega STs come with the blitter
chip built in.
The second major announcement was the Atari ST Desktop Publishing System.
An Atari ST "host" computer will serve as the front end for a laser printer
"engine." As of this writing (Wednesday night, before CES officially opens) the
manufacturer of Atari's laser printer has not been identified. (Perhaps Atari
will name names at their press conference at 9:00 Thursday morning.) However,
John Skruch at Atari told Antic Publishing the manufacturer was "one of the
three biggest names in the laser printer business." The Atari laser printer
promises virtually typeset quality electophotographic print technology with a
300 dot-per-inch resolution.
Third, and probably most unusual of Atari's new hardware announcements, was
the Atari IBM PC compatible. That's right -- Atari has jumped into Compaq,
Leading Edge and Hyundai territory by announcing their own IBM PC "clone" -- to

retail for an amazing $495. The new Atari PC features an 8088 microprocessor with a switchable clock speed of 4.77 MHz or 8MHz. The PC will come with 512K standard, expandable to 640K of RAM, plus 256K of screen RAM. As Atari's press information states, the PC "supports these graphics modes: enhanced color adaptor (EGA), color graphics adaptor, monochrome display adaptor and Hercules graphics cards." The resolution is 640 X 350, either monochrome or color. The PC is equipped with standard ports: parallel printer ports, RS232C serial port, plus built-in mouse support. Not surprisingly, it comes with a detachable keyboard (IBM PC/XT layout), and will accept a 8087 numeric coprocessor. The CPU box has a 360K 5 1/4-inch disk drive built in, and can accept two additional external drives. The PC's styling is similar to Atari's new STs -- either one would look sexy sitting on an executive (or home) desk. Atari hopes to use its PC as a front-end vehicle for their laser printer, and claims the PC will run "thousands of pieces of IBM software." And what was that graphics operating system software package we saw next to the Atari PC Clone? We'll get to that juicy gossip in our next report!
Those are the major Atari stories breaking before CES has actually started. Stay tuned to ANTIC ONLINE for more in- depth reports on Atari at CES. Later reports will focus on what's new in both 16- and 8-bit software and third-party peripherals for your favorite computers.

A Phoenix From The Ashes
Atari and The Winter 1987 CES

By Jon Bell and Matt Loveless
Editor, Consulting Editor, START Magazine

(Las Vegas -- January 8) -- "Now, in 1987, we are declaring war on the computer business in the United States."
These were the words of Sam Tramiel, as Atari kicked off the first day of CES with a 9:00 a.m. press conference at the Dunes Hotel.
"We are the number one computer in West Germany, in the home computer business and the personal computer business," he said, before adding that those interested could check with the German press and confirm that fact.
Atari's stance at the press conference wasn't merely confident, it was ruthlessly aggressive. The Tramiels made two points loud and clear: Atari Corporation has conquered overseas markets with its products, most notably the ST, and has established a firm foothold as a major player in the personal computer industry. The second point: Atari has now fulfilled its financial obligations to its patient former parent, Warner Communications, and is now no longer shackled to Warner. Atari's stock offering gave it an infusion of cash which enabled it to pay off its loan from Warner. According to an article in the December 15, 1986 issue of Business Week, Jack Tramiel flew to New York City and presented Warner Communications officials with a check for $36 million, thus effectively closing down Atari's debt.
(Late-breaking financial note: Atari's stock rose 2 1/2 points today, 17 1/2, up from 15. The stock has risen 6 points overall since it was first offered in November.)
Now completely free of the Warner mantle, Jack Tramiel has stopped looking over his shoulder at Atari's troubled past and is instead staring intently into his company's future. At the press conference, he reiterated his "Business is War" philosophy in no uncertain terms:
"The customer who supports my products knows what he wants. If you don't give him the right products at the right prices, he stops buying -- which is exactly what happened in 1985.
"Even giants, companies like IBM, have started to realize this and follow my footsteps, and keep reducing prices. That's the only way they can sell. And I'm not sure that they'll be able to catch up. . .
"IBM. . . gave their business to the Far East on a silver platter

because their prices were so high. And they just allowed all those people to compete with them. We at Atari have no intention of following their footsteps. We will try to always have the most innovative products -- constantly coming up with new products at the right prices. . . The philosophy continues, the philosophy is successful."

"THE FUN IS BACK"

Atari formally introduced its new product line, from revamped videogames to its IBM PC compatible, with a short videotape presentation.

Videogames, which sent Atari Inc. into billion-dollar-a-year profitability and then sent it spiraling almost into oblivion, have re-emerged at Tramiel's Atari Corp. The venerable Atari warhorse, the 2600, has been given a facelift and is now selling at a retail price of under $50. The new 7800 game system, which James Morgan introduced in those last terrible months before the Tramiel takeover, is heralded as the next generation of videogame. It includes a copy of Pole Position, and will retail for under $90. The 7800 features better than XE-quality graphics and sound, and will accept the new "Supergame" cartridges from such companies as Broderbund, Epyx and Electronic Arts. The first titles to be released include Karateka, Choplifter, Summer Games, One On One Basketball and Skyfox.

Sam Tramiel then mentioned a third new videogame system from Atari -- the XE System. It was displayed (not running) in a glass case at the Atari booth. The XE System is a small, squarish box which doesn't resemble a standard videogame. Its sharp angles and round, pastel buttons give it an unusual, almost art-deco appearance. According to Tramiel, it is fully expandable with a plug-in keyboard and disk drive, turning it into an introductory computer. It will be available 2nd quarter of 1987.

THE MEGA ST SYSTEMS

"I introduced the first personal computer 10 years ago," said Jack Tramiel. "It was called the PET. It was a 4K machine. . . Today we announced a 4-megabyte machine."

From 4K to 4000K in 10 years is an incredible feat of technological evolution, and the new Mega STs represent another link in that evolutionary computer chain.

As we mentioned in our first report, the Mega STs will be sold in 1, 2 and 4 megabyte configurations. They feature detachable keyboards (with improved, crisper keyboard "feel"), a separate CPU box housing a double density 3 1/2 inch drive, built-in blitter chip, expansion bus and power supply, and use the new one-megabyte DRAMs. A mouse port and joystick port are in the back of the ST keyboard unit, near the center. The keyboard itself is attached with a length of coiled cable, using standard phone jacks.

The usual ST ports (DMA, MIDI, etc.) are arranged in the back of the CPU box. The box also serves as a monitor platform. Atari's new 20-megabyte hard disk fits in the same "footprint" as the CPU and can be placed between CPU and monitor, adding only another inch.

UNDER $1500 LASER PRINTER

Conventional laser printers offered by other companies require hundreds of dollars worth of microprocessor and support electronics. But the Atari ST's high-speed DMA port, coupled with the raw horsepower of the 68000 microprocessor, allows the ST to drive their new laser printer directly, thereby lowering the price. At the show, Atari announced a desktop publishing system,

which will include a two megabyte Mega ST and an Atari Laser Printer, for less than $3000. The 300 dot-per-inch laser printer will also be sold separately for under $1500. A spring delivery date was announced.

In the Atari booth, a Mega ST2 (2-meg) was actually printing high-resolution, excellent quality press releases (about one per second), giving true meaning to the phrase, "hot off the press." Although Atari was reluctant to identify the manufacturer of the printer engine, experts recognized the show model as a Canon. The Canon engine is known for its low price. However, it supposedly has a limited print life. Also, it is good for small-quantity printing, but the per-copy price is relatively high. Antic Publishing was unable to determine if Canon will be the actual supplier for the final version. When asked at the press conference, Sam Tramiel identified the supplier as "Japan, Inc." (Editor's note: since Canon is not known for extremely low volume prices to OEM vendors (such as Atari Corp.), our assumption is that the final Atari laser printer will not use a Canon engine.)

Within 90 days we may even see a laser printer development kit, allowing software to interface with virtually any laser printer engine. This will open the market for third party manufacturers, both high- and low-end, and make the Atari one of the most versatile (and inexpensive) desktop publishing systems around. For less than the price of a Macintosh, you can get a Mega ST2, an Atari Laser Printer, and the software to drive it.

THE ATARI IBM PC COMPATIBLE

As we mentioned in our first ANTIC ONLINE report, Atari has announced the first in a proposed series of IBM-compatible computers.

There will be two configurations of the Atari PC: a $499 version, with a IBM PC/XT-styled keyboard and CPU only; and the $699 version, which will include a "tri-sync EGA monochrome monitor." (The actual PC hardware is identical; only the packages offered are different.) The monitor has a 720 X 348 high-resolution display. Both computers come with mouse ports and mouse, built-in parallel, serial and SCSI ports, one 5 1/4 inch 360K disk drive (built into the CPU box), and 512K RAM expandable to 640K RAM. They also include 256K of dedicated screen RAM, which makes the entire 512K of system RAM available to developers. Atari will also market an expansion box which will accomodate up to five AT-sized add-on boards.

The Atari PC comes with (unheard-of) graphics support built in: EGA (enhanced graphics adaptor), CGA (color graphics adaptor), Hercules and IBM monochrome. With an EGA monitor, the PC will support 640 X 350 pixels resolution. Most EGA monitors retail for over a thousand dollars, however sources at Atari indicate they are working on an extremely low-priced EGA color monitor. You can also hook up a standard ST 3 1/2 inch disk drive and read and write IBM laptop disks, making the transferral of text files in that format an easy task. (Note: this does NOT mean you can run ST software on the Atari PC.)

The Atari PC will be bundled with the GEM Desktop from Digital Research along with other applications. The "juicy gossip" mentioned in our first report: it is rumored that Microsoft Windows will be available for the PC. (Also, Windows MIGHT be available for the new Mega STs.)

Who makes the Atari PC? Unlike many of the compatibles on the market, Atari manufactures the PC in their 200,000 square-foot Taiwan plant, where they make all their equipment.

Atari officials quickly dismissed concern that their PC indicated any

abandonment of their ST line. John Skruch of Atari likened the situation to a software house manufacturing products for differing computers: Atari is an electronics company specializing in computers, and their PC is simply an entrance into another market. (You should also consider that Commodore is showing both their standard Amiga and an IBM PC clone at CES. Commodore has sold their clone in Europe for the last year or so, and are just now attempting to market it in the U.S.)

"The importance of this machine," says Sam Tramiel, "is that someone can take it home, open the box, and be ready to run. You don't have to plug in cards or extra things; you have everything you need, right off the bat."

THE FUTURE ATARI

Looking forward, Jack Tramiel proffered the following to the press:

"We almost started believing the press -- about how bad it [Atari's viability] really was. Well, the press is wrong. It seems that the customers want to buy the right product at the right price. 1986... was a fantastic year, and 1987 will be much, much, much better."

TOMORROW: NEW SOFTWARE, THIRD PARTY HARDWARE, AND 8-BIT COVERAGE. Read about Crystal Castles, Psion Chess, StereoTek 3-D glasses, the ADAP digital sound processor, and a new, hard-hitting, TV commercial pitting the XE against the Commodore 64. Guess who wins?

86. BINHEX and HEXBIN program listings and documentation.

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-12 17:07:00 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8701121707.AA25576@mitre-bedford.ARPA>
Source record: 117990
Body handling: HTML body converted to readable text

Recently Turbo BASIC was distributed in BINHEX format. The program HEXBIN, listed below, will convert the distributed version back into binary so it can be run using the DOS "L" command. BINHEX and the documentation for both is included for completeness; all of this is being posted per the request of Dan Fleysher, the author of BINHEX and HEXBIN.

NOTE: BINHEX and HEXBIN are V E R Y slow, as they are written in Atari BASIC. Plan on 10 to 15 minutes of CPU time to decode Turbo BASIC. But believe me, it is worth it.

-John Sangster
jhs@mitre-bedford.arpa
==========

From: Dan Fleysher
The precise definition of BINHEX output.

The following is the a collection of background messages on BINHEX/HEXBIN:

BINHEX and HEXBIN are BASIC programs written for the Atari 400/800 and XL (8-bit) machines, so they are excruciatingly slow. You really have to want to send a binary file to someone if you are going to use them! I never took the time to speed things up with machine language assist - anyone who wants to do so is welcome to it. (Please share your improvements with the rest of us, however).

The attachments below contain background on how BINHEX and HEXBIN work. The two messages which follow this one contain the Atari-BASIC source code for the two utilities respectively. I trust you have download capability, so that you do not have to re-type the source code into your Atari.

The most successful use of BINHEX and HEXBIN was for distributing the VT100 80 column terminal emulator and a VT52 over the last couple of years. Little more has been done since then.

My apologies to everyone who has seen this stuff before - just toss it out as you see fit.

Dan

Subject: HELP for the Tired Typer
In-reply-to:
From: Dan Fleysher

Exchanging home-brew BASIC programs within messages over the net requires a modem and a good upload terminal emulator program (such as

ATERM, distributed on the net in Oct. '82). Even with this set up, plenty of information can get lost in the transmission - e.g., inverse-video and graphics characters. Sometimes these are crucial when the BASIC program contains machine language assist in the form of text strings (rather than data statements).

I have written a pair of companion BASIC programs which enable the exchange of arbitrary files over the net with no loss of data. This is accomplished by converting the file to be sent into a text file containing hexadecimal characters, two for each byte of the original file. One of the programs does the conversion to hexadecimal format, and the other converts the received hex file back into its Atari-useable form.

Before I publish these two programs, I would like to invite agreement/disagreement on a standard format for exchange. The format I propose is:

```
message header, explanatory
text, and general comments
.START.
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
xxxxxxxxxxxxx
.STOP.nnnnn
optional extra text
```

The translator for the received program ignores all text until it encounters the record ".START." Subsequent records contain hexadecimal characters (x's, above) in convenient (although unspecified) record lengths. The receiving program translates the hex characters into bytes until it encounters the .STOP. record. The number that follows ".STOP." is a decimal checksum, computed by adding up all the preceding bytes encoded as hex characters. (The checksum limit of 10 digits corresponds to a file length of more than 78 megabytes of average data)

My programs use record lengths of 36 hex characters so that they fit easily on the 40 character screen. Although the programs are written in Atari BASIC, there is no reason they could not be re-implemented as machine language programs (for speed). These could also be distributed to the net using this facility.

Needless to say, this facility is proposed for exchanging PERSONAL or public-domain software only.

Opinions anyone?

Dan

Subject: Exchanging Binary Files over the net
From: Dan Fleysher

Last month I proposed a standard for exchanging binary files over the net in text messages by first converting them to hexadecimal. That message is attached.

I received an excellent suggestion from ken@ROCHESTER to add checksums to the end of each line, rather than just the end of the document, in order to enable easier recovery. Unfortunately I haven't had the time to incorporate this change, but my experience has been that if I receive a message at all, I get it without errors 99.999% of the time. I also received suggestions to look at KERMIT protocol, but I already have an reliable underlying transmission protocol - the message system.

Consequently, I am distributing two BASIC programs - BINHEX & HEXBIN - that can be downloaded and used to encode and decode binary files to/from hex (text) format. Someday, I'll convert them to machine language and redistribute them (I apologize for the performance of the BASIC versions).

In the meanwhile, if anybody uses them and finds bugs or has suggestions, I would appreciate hearing about your experiences.

Dan

87. SpartaDOS, MIO, Kyan Pascal, Deep Blue C...

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-12 20:34:48 UTC
From: btb@ncoast.UUCP
Message-ID: <1903@ncoast.UUCP>
Source record: 117991

I am writing this to find out what luck you all have had using SpartaDOS
on the 8-bits... I bought my 8-bit primarily because Kyan Pascal was
available for it, but even with the 130xe ramdisk, writing programs becomes
a hassle... I have heard so many good things about SpartaDOS, and the
US Doubler (file time/date stamping, double density, triple disk i/o speed,
etc. subdirectories...) that I finally went out and bought it recently...
it is tremendous at first use, but I have had problems using it... the
Kyan macro assembler doesn't seem to want to work with it...

Anybody else using this combination? Otherwise, it is trully great...
the ability to put both Express850 and Chameleon on a dd disk and run either
one and then the other without rebooting is nice... no reloading the
rs232 handler, etc...

Anybody have a memory map for SpartaDOS 3.2? (I will be talking to ICD,
but maybe somebody has one already on line?)

Hello fellow 8-bitters and SpartaDOS users!

88. Advice on Key re-assembly

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-12 20:42:42 UTC
From: Fleysher.wbst@Xerox.COM
Message-ID: <870112-124426-4845@Xerox>
Source record: 117992

Thanks for your input, those of you who responded. My "O" key now works fine - I squirted contact cleaner directly on the contacts. If any of you have old Atari 800's (circa 1979?) and need the following info for reassembling a key, read on; else delete.

I pried off the key cap, to expose the contacts, but the square plunger that holds the key cap and spring popped out like a jack in the box - it wasn't supposed to! The plunger is hollow and fits over the contacts which stick up from below. The contacts normally press together - a little horizontal plastic bar inside the plunger holds them apart until the key (and plunger) are depressed.

If I had merely pushed the plunger back into place the little bar would have mashed the contacts.

If a plunger pops out on you, you need a tool to hold the contacts apart so that the plunger bar can be safely pushed back down between the contacts. To make such a tool, I squeezed a plastic drinking straw into an oval cross section and cut off the sides of the oval for a length of 2 inches. That resulted in a pair of 2 inch parallel plastic tabs attached to the rest of the straw. I inserted the tabs thru the plunger (on either side of the bar), and down between the contacts to hold them apart while the plunger was re-inserted. Thank goodness it worked.

Sorry if this isn't clear. A picture would probably be worth a thousand words...

Dan

From: "GENE MERRITT" <F1.GDM@ISUMVS.BITNET>

I would like to know if anyone else out there is having trouble with their Gemini 10X printers. I have had mine for about 3 years now, and in the last four months it has started to act up on me. I have noticed an unusually large amount of friction between the ribbon and the printhead, caused by the ribbon shield that is attached to the printhead carriage body. This causes the ribbon spools to be spun somewhat freely on the return path and ribbon tension is lost. The loss of tension allows the ribbon to fall and it gets trapped under the printhead, or falls low enough that the head prints over it. I have folded a piece of light cardboard and placed it between the case and the spools and this succeeded in keeping the spools from freespinning but it did not cure my problem.

Aside from this, I have had no other problems with my printer and have throughly enjoyed owning it. I liked it so well that I convinced two of my closest friends to buy Gemini's.

Any suggestions? I would like to removed the ribbon shield but it is attached to the carriage and removal would require the disassembly of most of the printer.

thank you.

Source record: 117994

I believe OSS sells an ACTION! runtime package for "developers".
I don't know what they charge.

Somebody posted an alternative package on the net awhile back. It basically assists you in making a backup copy of your own cartridge's built-in runtime library and patching it so it will run off the disk. This sounds like "fair use" to me, so I have forwarded a copy to you directly. If anybody reading the info-atari8 posting needs it, please feel free to ask. The file is 421 lines long so I thought it best to spare those who don't need it.

-John Sangster
jhs@mitre-bedford.arpa

P.S. - I have also forwarded another useful ACTION! file which tells how to "chain" programs together in ACTION!.

91. OMNIVIEW price (correction)

Newsgroup: comp.sys.atari.8bit

I have recently mentioned CDY's OMNIVIEW 80-column upgrade for the Atari 8-bit computers to a few people on the net and it appears that I have been giving out-of-date price information. I understand that OMNIVIEW has come down from its earlier $59.95 price and is now selling for $39.95 list -- still including OmniWriter at no extra cost. (OmniWriter is CDY's 80-column word processor program for use with OMNIVIEW.)

In response to the request for a reposting, I'll toss in this 'offer.'

When we set up the Club II BBS in Detroit, we went out of our way to have the 'ultimate' ST selection. For quite a while, we managed, and established an incredibly library that was the first of it's size. We also set up an 8 bit section, which, all by it's lonesome (read 'by user input unexpected') got pretty epic as well.

Well, it seems there are so many ST files that people stopped uploading ST stuff. (They sure download though!) Since we, panicking, ran out and picked up a 30 meg drive, we're now sitting on 16 some odd meg left over. This could probably handle any 8 bit traffic you can throw at it.

My only consideration - we got countless uploads, but -quality- uploads are what matter. Because we hadn't 'aimed' for an 8 bit base, it was more important to us in the 8 bit section to keep worthwhile software. (The ST sections simply have everything in existence.) My definition of quality includes things like EXPRESS, TURBO BASIC, SpeedScript, etc. Many 8 bit users as well are allergic to supplying worthwhile docs. Good docs and support files also labelled something as 'worthwhile.'

Some of the things we went and removed in the 'great 8bit shakeout' were paint files (.pic), AMS files, and mindless BASIC games. I think everyone here however knows what's worth their time to call LD for. That's the real criteria.

So, given an overwhelming capacity for storage and close contact with the net, you may wish to archive net postingsof value there. If the volume of posting is too large, not to worry. I have another 30 meg drive I can plug in if necessary and I doubt there's 60 meg of PD 8 bit software in the world.

Terry Conklin
Club Network Coordinator
The Club II - USA (313) 334-8877
reply at: The Club (517) 372-3131

P.S. It's under Fido, so you'll need to look in the right (F)ile and (M)essage areas for 8 bit specific stuff. Also, if anyone's sitting on a 400 meg Vax or something that's obviously even more appropriate for a general access archive.

94. Re: Atari Artist & Movie Maker file formats wanted

> Micro-Illustrator files to an Epson printer. I'll post it if there is
> anyone interested.
>
> Daryl Monge
> AT&T Bell Labs

I would be interested in seeing such a program posted. I saw an article in an earlier ANALOG issue that contained such a program in BASIC, but so far I have not had the time to try to recode (or even redesign) it in ACTION! (I would also change it to work with my Toshiba P1340 printer, which uses Qume type control codes, according to the manual. Not exactly popular in the world of Atari software, but it prints well.)

My current problem is that I >>do not even own<< the Atari Touch Tablet/Micro-Illustrator (or any other T/T or drawing software)! I have only in the past 4 months or so become interested in owning a T/T or drawing software (having nearly abandoned all ambition of writing my own s/w once I realized what all was out there).

I had asked for an Atari T/T for Christmas - my wife and I exchanged "wish lists" - but my wife waited until the 11th hour to try to get me one, and after getting through to an Atari mail-order place in Columbus (from whom I had bought my 130XE), was told that

"there are no Atari T/Ts available, because Atari is engaged in a lawsuit with the mfr. of the T/T..." (same goes for the Light Pen, but I don't care) and
" the T/T has not been available for several months."

If ever was heard a discouraging word... Has anyone out there recently bought an Atari T/T? Is there no hope? I haven't seen a Koala Pad advertised for some time, so I wonder if THAT is available anymore either (I think Toys R Us and/or Service Merchandise locally used to carry that "pad"). The January ANALOG article mentioned also refers to a t/t called a "Powerpad". Does anyone know anything about that t/t?

I would appreciate hearing about this from anyone who knows
anything more. PLEASE reply by MAIL, because I don't get a
chance to read news often enough as it is, and I and my fellow
"ihuxl-ites" are being moved to a new machine this weekend.

Thanks in advance,
Nick DiMasi

(frusrated would-be "Atari artist")

95. uudecoder for Turbo BASIC files soon to appear..

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-14 04:46:38 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8701140446.AA04205@mitre-bedford.ARPA>
Source record: 117999

Howard Chu of U. Mich has promised to post the Turbo BASIC *** COMPILER and RUNTIME SYSTEM *** to complement the interpreter and manual that have been received by many on the net already. Howard says he will use unix uuencode to put the binaries on the net. Since not everyone has uudecode facilities on their host, I am hereby posting a "draft" version of my uudecode for the Atari 8-bitters. This is not very heavily tested, but it does appear to work. It may, however, not handle all the junk that the net can introduce into the file in transit, so let's hope for the best.

To run it, you must run Atari BASIC and "ENTER" this file, then RUN it. It may also work with Turbo BASIC if you have the interpreter up and running, but I haven't tried it. (It is pretty fast even with Atari BASIC, though, because the dirty work is done in machine language.)

I ask all who use this to report any problems they run into so perhaps I can make the final version more "robust". Thanks and here goes...

96. uudecode for 8-bitters

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-14 05:36:32 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8701140536.AA04771@mitre-bedford.ARPA>
Source record: 118000

I tried uudecoding the version of turbo basic that I posted in uuencoded form, using what I hope is the same version of uudecode I posted, and it worked fine. This is of course no proof that it will work after the hosts on the net get through with the uuencoded file, but at least there is a fighting chance!

-John Sangster
jhs@mitre-bedford.arpa

P.S. - It took about 15 seconds to do the uudecoding -- versus around 15 MINUTES or more with HEXBIN!

97. Re: REPOSTINGS // TURBOBASIC

Newsgroup: comp.sys.atari.8bit

I would be willing to post the compiler, runtime program, and docs
for Turbo Basic. Give me about 3 days to get things together. It
will be in HEXBIN format again.

Owen Alexander

98. Turbo BASIC compiler documentation

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-14 17:32:11 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8701141732.AA23453@mitre-bedford.ARPA>
Source record: 118002

Here is the available documentation on the Turbo BASIC compiler for the XL/XE computers. The compiler apparently turns Turbo BASIC (or Atari BASIC) source code into "P-Code", or a special language understood by the "Runtime System". Then to run it, you have to execute the Runtime System. The manual suggests putting the Runtime System on a DOS 2.5 diskette, naming it AUTORUN.SYS so it will execute on boot-up. Otherwise, RUNTIME might be a reasonable choice. (They suggest RUNTIME.COM, but since you will probably be using DOS 2.5, I see no reason to encumber it with .COM, which makes things easier ONLY with DOS-XL and OS/A+.)

The compiled BASIC program should go on the same disk. If you want it also to run automatically, it should be named AUTORUN.CTB. Otherwise, it can be given another name which should, however, end with .CTB for Compiled Turbo BASIC. Basically (so to speak), you would name the compiled file AUTORUN.CTB if you always want to run this program when you boot the disk, e.g. if it is the only program on the disk. Otherwise give it some other name.

The compiler and runtime system files will follow.

-John S.

(NOTE: A 40-col version of the doc file is also available.)
--------------------------------c-u-t---h-e-r-e--------------------------------

THE TURBO COMPILER

Documentation and Operating
Instructions
by Dave Arlington
Original Program by
Frank Ostrowski

This documentation is provided by the Western New York Atari Users Group and may be reprinted freely provided this credit is included.

I know everyone is still rubbing their hands in glee over TURBO-BASIC, the new public domain Basic interpreter imported from Holland and Germany. This month we are proud to present a new treat from our international friends overseas, the TURBO COMPILER.

The TURBO COMPILER will increase the speed of your TURBO BASIC programs 3-5 times and regular Atari BASIC programs can be speeded up to 10-15 times faster. Unfortunately, like TURBO BASIC, the TURBO COMPILER will only run on the XL/XE series of computers. In addition, the finished compiled programs will also only run on the XL/XE series.

The TURBO COMPILER is very easy to operate. It can be used with more than one disk drive, even Drive 8, the 130XE ramdisk. On the TURBO COMPILER disk, you will find several files. The important ones for the operation of the TURBO COMPILER are COMPILER.COM and RUNTIME.COM. Before you begin, you should prepare two disks. The first one should be a blank formatted disk with DOS.SYS and DUP.SYS written on it. Your second disk should contain your BASIC program (TURBO or ATARI BASIC).

To begin, insert the TURBO COMPILER disk into your drive and turn your computer on. When it has finished loading you will be in TURBO BASIC. Type DOS to get to the DOS 2.5 menu. Choose DOS Option 'L', Load Binary File and load the file COMPILER.COM. After a short while, you will see a screen full of German. If you do not read German, do not worry, that is what this article is for! At any time that you are on this screen, you may reboot your system by hitting Control-R or you may return to DOS by hitting Control-D. You will be asked if you really want to do this. If you do, don't forget to 'J' for Ja and not 'Y' for Yes!!

To compile your programs, remove the TURBO COMPILER disk from the drive and insert the disk with the program you want to compile. (If you have two drives, insert your disk with the program to compile in Drive 2 and the blank DOS disk in Drive 1.) Press the number 1 key (Number 2 if you have two drives). A complete listing of all the files on that drive will appear on the screen with one highlighted in inverse video. Using the arrow keys, highlight the file you want to compile and hit Return. That's all there is to it!

At the top of the screen, you will see the line numbers fly by as the program is compiled. When it is finished, you will be prompted for a file name to save your compiled program under. It has to have an extender of CTB (for Compiled Turbo Basic). The program will not let you use any other extender. At this time, if you have one drive, you should remove your disk with your original program on it and replace it with your blank DOS disk. If you want your compiled program to be an AUTORUN file, you should name it AUTORUN.CTB. Then the file will automatically load and run at bootup time.

There is one more step that you must do to get a completely runnable compiled program. Go back to DOS and copy the file RUNTIME.COM from the TURBO COMPILER disk to the disk with your compiled program on it. Rename the RUNTIME.COM file to the name AUTORUN.SYS. Your disk is now ready to go. The TURBO COMPILER does not compile to runnable code, you must run the RUNTIME.COM file to run your compiled program.

One technical note on the TURBO COMPILER: If you're not familiar with other compilers for the ATARI computers, you should know that many have trouble compiling certain types of statements or insist that you organize your program structure in a certain way. So far none of these problems have occured on any programs we have tested with the TURBO COMPILER. The only statement that wouldn't compile so far is the END statement. The only program structure that we have had trouble with is a FOR-NEXT loop that has two or more NEXTs for one FOR. For example:

```
10 FOR X=1 TO 5
20 IF X=3 THEN NEXT X
```

```
30 NEXT X
```

Other than those two examples, we have had no problems compiling any type of program, either TURBO or ATARI BASIC. Please let us know of any problems you run into compiling any types of statements or programs.

Whether you program in TURBO BASIC or just want to turbocharge our old Atari BASIC programs to super speed, I'm sure you will find the TURBO COMPILER will fit all your speed needs.

---

99. Using Uudecode on the Atari (or anywhere).

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-14 21:38:05 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8701142138.AA01717@mitre-bedford.ARPA>
Source record: 118003

The Atari 8-bit Uudecode I posted earlier will want to see a file starting with a line "begin nnn filename". Or at any rate it should start with the word "begin" as the first 5 characters. The file should end with (usually) a short line, a line containing just a space in the first position, and finally a line saying just "end" (3 characters followed by a RETURN).
You will have to edit the messages received over the net to put each uuencoded program into a separate file with no extraneous characters. Once you are in that state, run Atari BASIC, type ENTER "D:UUDECODE.LST, and RUN.

Tell UUDECODE you want to Decode (D) and give it the desired input and output file names, including device specifications. It will do the rest.

You may find it convenient to SAVE the uudecode program as UUDECODE.BAS, as .BAS files load much faster than .LST files.

-John Sangster / jhs@mitre-bedford.arpa

Howard Chu has kindly forwarded precise byte counts for the Compiler and Runtime files. Having been through this before, I know it is useful to be able to check these values before proceeding. If you have the wrong number of bytes after decoding, you are in trouble.

I suppose somebody should write (or post) a utility to count the bytes. I did this on my host system at work last time. I guess it wouldn't be too hard to add to uudecode. I'll leave it as an exercise for the student for the moment.

-John S.

Subject: Compiler miscellany

I should have sent this out first - here are the byte lengths for
the two files, decoded:
Compiler.COM -- 9974
Runtime.COM - 10920
Hope things worked out....

I have attempted to modify UUDECODE.LST so it counts bytes while it is processing a file and displays the result at the end. This is not tested, and, while I like to think such a simple mod would work right the first time, well...

Somebody let me know if it gets the same values Howard did.

-John Sangster / jhs@mitre-bedford.arpa

If it works, delete the old one and rename this UUDECODE.LST (or .BAS if you SAVE it).

102. Atari 1200XL Chroma

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-15 00:35:08 UTC
From: wrd@tekigm2.TEK.COM
Message-ID: <1375@tekigm2.TEK.COM>
Source record: 117906

Recently Richard Andrews answered how to hget chroma out on the 1200XL, however, as I asked him:

Appreciated your answer. However, one slight problem -- not being an electronic engineer, I do know which is the emitter of Q7 on the 1200XL. Having a spare mother board in front of me, I see that:

the left hand leg goes to C61 (? -- 1 is covered by component)
the middle leg goes to R31
the right hand leg goes to R43

Question: which leg is the emitter?

If anyone else on the net has the answer, please post it. I have previously posted similar answers, but have tried to keep the answers in terms that even I can understand -- then I figure anyone can do it. Since the circuit board has all components labelled, it is a fairly easy task to trace out each leg to see where it goes, but to determine whether it is the emitter or not (particularly - as I understand it - these transistors do not have a standard configuration). If I get an answer, I will post it, as Richard and I cannot be the only ones using 1200XL's!

--Bill Dippert--

103. Re: Compiled Turbo BASIC example.

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-15 05:57:13 UTC

appear at the top of the article:
ANTIC PUBLISHING INC., COPYRIGHT 1987.
REPRINTED BY PERMISSION.

Atari at The Winter 1987 CES
Software and Wrap-up, Part 1.

NOTE: I'd like to personally apologize to those of you waiting to get an CES update on Saturday, as we promised. What our people at CES and our people back at Antic had was, in the words of Strother Martin from "Cool Hand Luke," a "failure to communicate." CompuServe's Marty Isaacs and Ron Luks of the Atari SIG enabled us to update on Friday, Saturday and Sunday, although a misunderstanding on my part resulted in our article not appearing on Saturday. Therefore, our Saturday report on new software and hardware is now part of this CES wrap-up, and should conclude tomorrow.
I'd like to thank Ron Luks, and most especially Charles Jackson, Antic Online's Editor, for their valiant efforts in keeping the Atari community informed. For their part, they are blameless.
Jon A. Bell
Editor
START

THIRD PARTY HARDWARE AT CES

By Matt Loveless
Consulting Editor
START

12/Jan/1987
Hybrid Arts Inc., the software and hardware with a reputation for putting out the best MIDI software in the industry, showed one of the most exciting new products in the Atari world: The ADAP Soundrack. ADAP stands for Analog to Digital Processor. It's a $2000 hardware plus software system, built in conjunction with Nilford Laboratories, Inc., for the Atari ST, designed to replace equipment costing over thirty times as much. The basis of the ADAP is a racey black rack mount box with sound input and output lines, plus an interface box which plugs into the cartridge port of a one- (or more) megabyte machine. What does it do? Digital sampling. And it does it well.
Digital sampling is a process where sound is converted into digital patterns which a computer can store, manipulate, and play back at will. Compact discs have been using this technology for years now. Sound enters the ADAP box from virtually any sound source (such as a compact disc player) and is converted into digital signals in the ST's memory. Once the sound is in the ST, it appears as a digital waveform in a window in the center of the screen.

You can examine the waveform by zooming in or out on either the X or Y axis, or even both. You can scroll along the waveform to see its entirety, or even sample more than one sound and switch between them.
Hybrid Arts claims the system can sample at a rate of 44.1 Khz with 16 bits of resolution -- that's compact disc quality! It even samples in stereo. Once a sample is made, it can be played back at the push of a button. The sound is phenomenal. But ADAP doesn't just let you record samples. You can also edit them. You can cut, copy, and paste portions of a sample. You can even do mixing, looping, or modify the actual waveform freehand.
The ADAP system replaces some super-sophisticated musical sampling equipment by allowing you to "play" the samples from your MIDI keyboard, polyphonically, with up to eight voices going simultaneously.
- On a one-megabyte machine, allows 80 seconds of sampling at full 16-bit linear resolution at 10 Khz. Allows 20 seconds at 44.1 Khz.
- Fully MIDI compatible
- Polyphonic
- Storage of up to 64 multi-samples in memory for instant playback.
- Real-time digital effects processing (delay, echo, reverb, etc.)
- Real-time oscilloscope
- Direct from compact disc, digital to digital sampling.
- Multi-sample keyboard splits.
- Compatible with the new MIDI digital sample dump data standard. Will work with data from other MIDI sampling devices.
- 19" black rack-mount case.
- Suggested retail price is $1,995.

When asked why they chose the Atari ST as the host sytem, Frank Foster, president of Hybrid Arts, replied: "It's not like we actually 'chose' Atari. It simply couldn't be done on any other machine. Not on an Amiga. Not on a Macintosh." Now that's a compliment.
Other music news: Electronic Music Publishing House has MIDIPLAY, a real-time MIDI record/playback system which supports all 16 channels of MIDI information. List price is $49.95, and a demo disk is $5. They also have Musidisks, a series of pre-recorded data disks of everything from Bach to the Beatles. List is $19.95.
We will be covering the exciting world of MIDI, music software and the ST's role in music composition in future issues of START.

STEREO 3-D GLASSES PLUS NEW SOFTWARE TITLES
The Catalog software division of Antic Publishing was showing, center stage at the Atari Booth, the 3-D StereoTek Liquid Crystal Shutter Glasses along with some spectacular demos of upcoming software. The new releases include Wanderer, a point-of-view space game, CAD-3D 2.0, CyberMate, the much anticipated stereo modeling and animation system, a molecular modeling program, and Stereo Maps & Legends. Certainly the most impressive demo was the world-premiere of Tom Hudson's SteelyBoink!, a stereo ray-tracing demo illustrating a simulated depth of 8-10 inches into the ST's monitor. START Magazine will be presenting a version of the SteelyBoink! demo which does not require the StereoTek glasses on Antic Online in February. This will highlight Tom's ray-tracing article in START #4 (available in March).

A SMATTERING OF NEW ST SOFTWARE

The following represents only a few of the many ST programs shown at the Winter CES. New products information and reviews of both these and any omitted programs can be found in upcoming issues of Antic and START.

Firebird, of Ramsey, New Jersey has several new programs for the ST. Universal Military Simulator lets you create your own combat scenarios, or even enter in the parameters of real battles and then modify them "to explore the 'what if' possibilities." Tracker is a shoot-em-up arcade game which combines a huge playfield with artificial intelligence routines. Your deadly enemies, the Cycloids, remember your play tactics and try to prevent you from using them again. Golden Path is a new animated illustrated graphics adventure game. You use the mouse to control your character through 45 screens of graphics and animation. All three games should retail for $44.95.

WordPerfect, the best selling and highest rated full-feature word processor for the IBM PC, is now a reality on the ST. WordPerfect Corporation was demonstrating a prerelease version of the product at the Atari booth.

The Atari version of WordPerfect features the best of both worlds: it is GEM based, using menu bars and windows, but it also supports the full array of keyboard commands familiar to users of the IBM version. Additionally, users moving from the IBM to the Atari version will also benefit from full file compatiblity with WordPerfect 4.1.

The program uses high-speed assembly language routines for ultra-fast response times. I gave it the acid test and found it faster than any other word processor for the ST, faster even than ST Writer, the venerable speed-demon. WordPerfect supports footnote and endnote compilation, full keystroke macros, automatic calculation of numeric tables with the built-in math mode, complete database merge capabilities, an outline feature, a nine-keyword sorting facility for alphabetizing lists, a 115,000 word dictionary, including legal and medical terms, a five-level table of contents and index generator, a five newspaper-style columnar display, a sophisticated thesaurus, a three-level undo capability, and a virtual memory data system, allowing data to flow onto disk when computer memory is full.

This will clearly be the most sophisticated word processor for the Atari ST, taking full advantage of the new one, two, and four megabyte machines. WordPerfect for the Atari is scheduled for release second quarter, 1987. The suggested retail price is $395, although a representative from WordPerfect indicated Atari users should be able to purchase it in the low $200s.

Timeworks has released their three powerful productivity software for the ST: Word Writer ST, a word processor, Data Manager ST (covered in the Brian Lee's Database Overview in START #4. out in March), and Swiftcalc ST, a spreadsheet. The Timeworks programs are designed as an integrated package. Suggested retail is $79.95.

A QUICK LOOK AT THE 8-BIT FIELD

Although not as numerous or as flashy as the new ST software, there were several companies showing software or distributing information for the 8-bit Atari line. These companies shared a half-dozen XE computers, which sat alongside the new XE [game and computer] System, the new 8-bit 3 1/2 inch drive, and Atari's 1200 baud XE modem (which will also work on the STs). Prices on this hardware have not yet been set.

New from Hi-Tech Expressions is AwardWare, a program allowing you to

custom-design and print awards, certificates, ribons, tickets, coupons and checks. The program includes templates for your forms -- just type in your message and you're ready to give someone that special greeting! Retail price is $14.95. Also from Hi-Tech is CardWare, an animated birthday card, for $9.95; PartyWare, card and party design kit with database of friends and events, for $14.95; HeartWare, an animated greeting disk and love note maker (let a machine do the mushy stuff for you), $9.95; and WareWithAll, which includes colorful stationery, envelopes, stickers, markers, and disk labels, for $14.95.
ICD, Inc. was promoting their large array of 8-bit Atari products, such as P:R Connection, an interface allowing your XL or XE to run a large variety of disparate printers and modems; the Printer Connection, a "smart" cable which will make your 8-bit Atari compatible with any Centronics parallel printers; Multi I/O, a box which gives you a RAMdisk, parallel printer interface, serial printer and modem interface, a printer spooler, and a hard disk interface; an 80-Column Adapter, which plugs inside of the Multi I/O case; US Doubler, a chip set which gives your 1050 drive true double density and an accelerated I/O rate; SpartaDOS Construction Set, ICD's custom DOS; SpartaDOS X, a cartridge-based DOS; R-Time 8; a piggyback cartridge clock; and RAMBO XL, a program enabling your 800XL or 1200XL to make use of 256K of RAM (you supply the DRAM memory chips).
Zobian Controls was promoting RAOS (Rat Actuated Operating System), their operating system giving your XE a GEM-like OS, including pull-down windows, a mouse-controlled arrow-pointer, and icons. Zobian also has improved their mouse, originally called the Rat. The SuperRAT is now a two-button digital mouse, which works in conjunction with the Zobian DESKTOP program Z-DOS (included in RAOS). The SuperRAT/RAOS combination sells for $99.00.

107. Turbo BASIC compiler, Magic drawing program...

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-15 18:44:36 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8701151844.AA29628@mitre-bedford.ARPA>
Source record: 117911

The compiler and runtime system programs posted to the net may not work.
I have not been able to make them work using the VAX Uudecoder and downloading
with kermit. I assume the VAX uudecode program is working correctly, and it
produces an object file that begins "01FEFFFF", not a promising omen if it is
to be a load module. I get the same thing when I download it. I have not
tried my own uudecode, but I assume it will agree with the VAX. Howard Chu
will look into it on his end, but meanwhile don't be surprised if you are told
"Bad Load File" when you try to run the compiler or runtime module.

Also, I seem to have given bad information in a previous posting re: Magic.
Here is a correction from Howard:

108. filename extensions for Turbo BASIC

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-15 20:07:51 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8701152007.AA01708@mitre-bedford.ARPA>
Source record: 117912

Does anybody know what the "official" filename extension for Turbo BASIC files is? I know that .CTB was used for compiler output files. I suggest .TBA for Turbo BASIC source files and .TLS for LIST files. If the file is compatible with Atari BASIC then the standard .BAS and .LST should be used for the tokenized and ASCII source files.

I don't like .TUR because it gives no clue to the language. Somebody might write Turbo PASCAL for the Atari and .TUR would be just as valid for that as for Turbo BASIC.

Does anybody have any comments?

Does anybody care?
-John S.

109. Turbo Basic and Time

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-15 21:35:53 UTC
From: hans@umd5
Message-ID: <1418@umd5>
Source record: 117913

The Turbo Basic interpreter which was posted recently assumes 50Hz vertical
scan rate for its timing functions, and therefore gives erroneous results.
(On machines using 60Hz, of course).
Following are changes which should rectify that situation.
Warning: I have arrived at these by looking at disassembled code, and have
not had a chance to test them.

Apparently there is a statement of the form
TIME HOURS,MINUTES,SECONDS
to set the time. It multiplies seconds by 50 to get the jiffy count. It is
simple to change that to a multiply by 60. To do the exact conversion would
require somewhat more work, and I am not able to do that at this point.

Address old new
FBA6 F2 16
FBA7 FB FC . change JSR $FBF2 to JSR $FC16

If you want to change the BINHEX file, change line 946 (counting .start. as
line 1) from
FC20C4FBC93CB01C20DEFB20F2FB20ECFBA5

____
to
FC20C4FBC93CB01C20DEFB2016FC20ECFBA5
Of course the checksum will be incorrect after you do this.

The TIME function returns the current jiffy count.
The TIME$ function has a constant of jiffies per day built in, at address
FB6E to FB73. The built in value is $430432000000, or 4320000
(which is 50*60*60*24). This could be changed to one of the following:
a. $430518400000 for a scan rate of 60 Hz.
b. $430517882052 for a scan rate of 59.94005233 Hz.
c. $430517737658 for a scan rate of 59.92334 Hz.
The first case has the advantage of being compatible with the TIME command
above, but it will make the clock loose about 86 seconds per day.
The second case uses the standard scan rate (see recent rec.video and
comp.graphics posting).
The third value is taken from "Mapping The Atari", Revised edition, page 182.
I do not know what its justification is. The difference between b and c
should be about 24 seconds per day, the difference between a and c about
110 seconds per day.

To make the change in the BINHEX file, change line 943
from
05E6F260410256000000430432000000002000
----
and fill in your favorite value.

I have no idea how accurate the crystals in Ataris are. And then there is the problem of loosing scan counts when VBIs are disabled ...

Again: I hope this is useful, but I have NOT had an opportunity to test it.

110. Re: Turbo Basic and Time

Newsgroup: comp.sys.atari.8bit

Atari at the Winter 1987 CES
Wrap-up, Part II -- Errant thoughts.

By Jon A. Bell
Editor
START

13-JAN-87: Those readers who have never been to a Winter Consumer Electronics Show have little conception of the actual work involved in covering the events. The show is sprawled across the enormous Las Vegas Convention Center (several huge buildings the size of, say, dirigible hangers), the surrounding hotels' convention rooms and hotel suites. Readers should be aware that CES CAN be a lot of fun -- the only drawback is time and your personal stamina. For the businesses involved (including Antic), CES is a great deal of handshaking, talking, meeting with advertisers, computer dealers and retailers, giving out business cards, handing out magazines, soliciting articles for those magazines, business lunches, and writing articles for ANTIC ONLINE (to the best of our ability). It's not a pleasure trip. Finding the time, after work commitments, to see the latest compact disk player or car stereo is difficult. After you've been on your feet for 12 hours a day, you don't want to do anything but tear off your too-tight tie, go back to your hotel room and collapse, or else look in the Yellow Pages under "foot transplants." (Actually, to some extent this weariness is to your advantage. You're too tired to throw away money on gambling, although I found the time to improve Las Vegas's roads and school system to the tune of $10 at the craps tables. I would've been better off putting that money towards a pair of sensible shoes for the show. I wore black leather shoes the first day. I wore Hush Puppies and bandages the next three.)
A great deal of Antic's handshaking and elbow-rubbing (both figuratively and literally) was at the always-crowded Atari "booth." Atari's display at the Consumer Electronics show was a huge assemblage of black plexiglass panels, right at the entrance of the West Hall. Atari's location was terrific -- their display was the first thing you saw when you walked into the building. (We've avoided pointless Commodore-bashing, but for those interested in the competition, Commodore DID attend, and had an impressive two-story booth in the middle of the building. They were showing their PC 10 and 11, IBM clones to retail for slightly under $1000. They also, of course,

were promoting the Amiga. I breezed through the booth during set-up day [Wednesday], and didn't return. My conclusions? Commodore now has to compete with Jack's Atari -- and his prices -- on both the ST/Amiga front and now the IBM PC front. The only negative thing I'll say about Commodore is that Atari's booth position was much better.)

The black Atari panels were festooned with the specifications of their new products (such as the Atari PC and the Mega STs), the names of ST software developers, and housed many color monitors showing various demos. (Funny note: One of the public domain DEGAS screens flashing by on the monitors depicted a PC with the caption, "How do you spell boring? I - B - M." Guess that one slipped by the new PC-promoting Atari.)

In all, there were about 20 STs, mainly 520s, which were shared by software developers. Many of the developers demonstrated their products in shifts. Atari had 2 of the new Mega STs (both 2 megabyte versions -- Mega ST2s); one sitting next to Antic Software's StereoTek glasses display, the other connected to the Atari laser printer. Half-a-dozen XEs were on display; XLENT software, LCD Inc., and Zobian showed off their new wares. XLENT had Typesetter Elite (soon to be reviewed in The ST Resource), and Miniature Golf, by Dave Plotkin. XLENT's Jennifer Brabson showed me an amusing book of her own cartoons, which you might be seeing in one of our magazines or in computer graphics form in the not-too-distant future. One of her caricatures depicted Tom Hudson, wearing a plaid shirt and slacks (accurate observation: Tom hates suits), sitting at his CES ST keyboard demonstrating DEGAS Elite.

Atari also showed their new 1200 baud Hayes-compatible modem, a sleek beige box approximately 6" wide, 10" long and a little over 1" high, which they introduced at Comdex. Retail is around $99. An odd piece of Atari XE hardware was their cassette program recorder -- the XC 11. Although some people on a VERY tight budget might want to buy it, statistically speaking, the majority of 8-bit owners have disk drives, and cassette-based software might be difficult to find.

One (intentionally) funny aspect of the Atari show was a new 30-second XE commercial, which ran over one of the monitors in the XE section. (Atari also showed the commercial during the videotape presentation at their Thursday morning press conference.) The commercial shows two young boys sitting at two computers -- an Atari XE and a Commodore 64. As they type away, the Commodore boy looks over at the Atari boy, smiles smugly, and -- no kidding -- his head expands. It rises up (an inflatable makeup appliance) right under his beanie. The Atari boy looks over at him, and HIS head expands, slightly larger. Then there is a voice-over saying that the XE has better graphics, sound and games than the 64, while both boys play musical head expansion. Finally, as the voice concludes, "The Atari blows the Commodore out of the water," the Commodore boy's beanie flies off, and his head -- and ego -- deflates. This must be a new trend in the computer industry, for Epyx Software has a commercial where a kid is playing a videogame and becomes so excited his head EXPLODES, then re-integrates itself. Who's the head of these advertising agencies -- David Cronenberg?

We now come to normal kids. Back to back with one wall of the ST display out of view was an open-ended room with Atari's reworked 2600 and 7800 game machines, these also hooked up to monitors, showing Crystal Castles, Pole

Position, Centipede, Joust, Battlezone (!) and other Atari classics. A charming touch was the presence of local children, dressed in Atari warm-up suits, who were demonstrating the videogames for the benefit of us repressed, three-piece-suited adults. (Note: General attendance to CES is limited to those 18 and over. The children were there by special permission.) I walked up to a game playing on a 7800 system and idly picked up a joystick. An angelic blond 9-year-old boy, who should've been out playing with June Lockhart and Lassie, picked up the other joystick and politely asked me if I would like to play against him. "Sure," I said, smiling indulgently. Five minutes later, the lad's razor-honed videogame reflexes had blown me away. My smile faded and I stomped off, grumbling.
Some final software news: Psion Chess will be distributed by Atari. No price has been set. Electronic Arts is putting the finishing touches on their Chessmaster 2000, a fantastic ST chess game they are porting over from -- you guessed it -- the Amiga. I had the opportunity to play it during an Electronic Arts party, and it was very colorful, very fun, and VERY difficult. Retail should be under $50. (A review of ST chess programs will be appearing in an upcoming issue of START.)
Thanks for bearing with us. We've tried, despite various technical gremlins, to give the Atari community as much information as quickly as possible. Among other features, we hope to present DIGITIZED PHOTOS on ANTIC ONLINE which you can view. Our goal is to become one of the fastest sources of Atari information (including visuals) short of a business report on CNN.
Again, thank you, and keep watching ANTIC ONLINE for programming tips, graphics demos, and late-breaking news reports from the Atari community.
****
[I'd like to personally thank Wayne Wilcox for downloading these CES reports from CompuServe so I could post them here]

114. turbo basic

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-18 00:06:33 UTC
From: wilmott@topaz.UUCP
Message-ID: <8435@topaz.RUTGERS.EDU>
Source record: 117918

Well, I just spent the afternoon trying to get the Turbo Basic
Compiler and Runtime package to work, but with no luck at all.
The posted UUDECODE program doesn't seem to work for me- all
I end up with is an "empty" output file. I've checked it over
several times and I give up. Anybody have any similar
problems? Any suggestions as to what went wrong? Or
better yet, is anybody who has a working copy willing to
copy it for me if I mail you the disks? (I have a working
copy of TurboBasic from last month, so I'd *really* like to
get the compiler and runtime package for it.)
Thanks for any help you may offer.

-Ray

I am a relatively new user, owning a 130XE, and I am looking for some help with the following:
1) Does anyone have a termcap for 850 Express, Amodem, or Tscope? I hope that at least one of these is more powerful than the BSD termcap 'dumb'. I would really like to run EMACS from home. It's such a help for serious work.
2) Does anyone know how to upgrade a 130XE to 256K (or more)? I read somewhere (here, I think) that the Newell upgrade, and ICD's Rambo XL will not. Is it possible to connect the RAM more directly, since the memory management scheme is already in place? If anyone has tried this or has any helpful information, please send me E-mail.
3) Thanks to John Sanger and Howard Chu (and whoever else is responsible) for the uudecode and binhex/hexbin utilities, and the Turbo basic runtime package. The binary encoding is just what I've been looking for, and the Basic package is critical, considering just how much is done for 8-bit machines in Basic.

My address is:
greg@cvl.umd.edu (ARPA)
seismo!mimsy!cvl!greg (UUCP)
Thank you all for your time & forbearance.

Source record: 117921

Well, I hope everybody out there has had better luck that I have in running Turbo BASIC. I STILL don't have working versions of the compiler and runtime system, though Howard Chu is making one more attempt to send me good files.

(Owen Alexander, I may have been hasty in saying I did not need you to send me your copies...)

Also, I wonder if it is just my copy of the Interpreter or is there a serious bug in the official copy: Mine seems to work, but when I ran a program that did some simple math like computing 2^(-1/12), it bombed with an error message "Error 11 - Overflow". Also, simple things like EXP(.5) threw it for a loop. Has anybody else found problems like these or do I need a new copy of the Interpreter file also?

-John S.

(They SAID it was too good to be true...)

I have faithfully collected every single extended memory upgrade file I have ever seen and kept them all in a group on the Club II in Detroit. I am not sure if there is an XE specific upgrade doc file (there are 30 or something like that.) is online, but if not, I will write up the docs on it since a friend of mine is proudly tapping away on his 512k XE (does that make it a 520XE?) and has been for months.

I am also know someone with a 2 Meg XE, though I wont encourage this as I have yet to justify the intelligence of putting 2 Meg into a 6502 computer with 1/3rd of it's CPU shut off.

Note, for anyone who was interested, that I do not have the specs for the M: memory management device that I described on the net sometime back. (Though I would be interested in feedback.)

(In fact, the famous Howard Chu has been known to stop by the Club II ;-)

121. Questions on Turbo Basic Compiler

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-21 14:02:05 UTC
From: store2@ihuxi.UUCP
Message-ID: <1478@ihuxi.UUCP>
Source record: 117925

1) Has anybody gotten the uudecode program written in basic to run?

My experience is that the program complains there is no end of file statement.
So to download the compiler, runtime, and magic files I went through the
following procedure.
I ran the uuencoded files through a uudecode program that runs on a vax. I then
downloaded the binary files to my XL atari. I then proceded to try and run the
compiler. I got the title page for the compiler then the machine hung.
It required me to power cycle the machine to gain control again.

2) What DOS/s does the compiler run with?

I tried Atari DOS, Sparta DOS, Smart DOS, and DOSXL with the same end result, except
for Atari DOS. When I ran the compiler under Atari DOS it returned to the DOS menu
rather then hanging the machine.

3) Is there any documentation to go with the compiler?

I have the documentation that came with the Turbo Basic Interpreter, but it doesn't
say anyting about the compiler.

4) Does the compiler try to determine if the machine is 130XE with extra memory?

I have upgraded my machine with the 256K memory upgrade that is not compatible
with the 130XE. I should also note the the Turbo Basic Interpreter runs fine on
my machine.

Wayne Wilcox

123. ACTION COMPILE TO DISK

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-21 20:03:42 UTC
From: curzon@kaoa01.dec.com
Message-ID: <7718@decwrl.DEC.COM>
Source record: 117927

Action language hackers: many people probably already have this compile to disk program. This is one of the Action modules by Clint Parker made available by him thru his BBS and the OSS BBS (not public domain, but may be used in "not-for-profit" ways). Some of them have appeared here, but I don't think this one has. (thanks to BL for this)

It's really Exhibit A to my problem:
"Why do I run out of memory when I compile a large program to disk?" (error 14 - I think). I trust it doesn't compile to RAM at the same time... else what's the point! & how can I fix it to direct output ONLY to disk? This stuff is a bit too tricky for me...

In article <1478@ihuxi.UUCP>, store2@ihuxi.UUCP (Wilcox) writes:
> 1) Has anybody gotten the uudecode program written in basic to run?

I didn't try to decode the compiler, but I did try the uudecode basic program on a 7500 byte Atari binary file I had on my UNIX machine and it worked fine. I uuencoded the file on the UNIX machine, changed the ascii new-lines to atascii EOLs, downloaded the file using x-modem, and uudecoded it, and it worked perfectly.

> 2) What DOS/s does the compiler run with?

I have a different copy of the compiler and it works fine with Atari DOS, and would expect it to work with the other flavors of DOS also.

> 3) Is there any documentation to go with the compiler?

I have a copy of the documentation posted earlier for the compiler if you need it.

> 4) Does the compiler try to determine if the machine is 130XE with extra memory?

The compiler only uses the standard bank of XL machines and does not use the extra banks of a 130XE or 256K XL.

I've been using Atari DOS 2.5 for far too long and have started
to get annoyed with its menu-ness.

I would be interested in finding out what other command interpreters/DOS
systems are available and what people think of them.

Please mail me with opinions on systems, who makes them (PD/Commercial),
how much they cost and your experience with them.

I know that OSS makes some neat stuff. I am curious what else is out there.

I will summarize the responses to this newsgroup.

129. Re: 800xl expansion port

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-23 21:51:45 UTC
From: jhs@MITRE-BEDFORD.ARPA.UUCP
Message-ID: <8701232151.AA01082@mitre-bedford.ARPA>
Source record: 117933

The expansion port is basically a direct connection to the 6502 processor bus. A couple of additional signals are also present, like cassette audio in/out (?). There is also a line called "External Select" which has to do with whether external devices or ones in the Atari console get the bus. I am not certain how this works but suspect that it is supposed to be generated in the external device to let it pre-empt the bus when it feels like it. That would seem to give the best flexibility for expansion.

Mapping The Atari, 1985 edition, contains a fairly complete description of the pinouts in one of the appendices. Note that the connector is a perfectly standard 50-pin card-edge connector, but the pin numbering used by Atari and reproduced in Mapping... is not standard. So be careful with pin numbering, especially if you use a standard connector instead of one purchased from Atari. The relationship between the two numbering schemes is simple, so there is no problem using a standard connector and making the translation.

I am not at home now so don't have detailed information readily at hand.

Message-ID: <8701232253.AA02295@mitre-bedford.ARPA>
Source record: 117934

Anybody who has had trouble using the uudecode I posted earlier (getting empty output files for example) should make sure that they are properly translating newline characters into Atascii newlines. This can be done before, during, or after downloading.

Perhaps I can take care of this translation inside the program in the final version. I am not sure this is what is causing the problems that have been reported, but it sounds like a possiblity.

You cannot use the parallel printer port on the 850 for use like that.
The only way to present data in that fashion is to use the joystick ports
for that. I have built an eprom programmer using that method, and found
that I could transmit and receive data about twice as fast as the
SIO bus. If you need additional info let me know. It isn't as hard as
it sounds. It could be done with basic. BTW I was sending serial data at
a undetermined baud rate.

Don't forget that you may have to buffer the output lines.

133. Re: help (memory upgrades/SpartaDOS/MIO, etc.)

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-25 23:42:32 UTC
From: btb@ncoast.UUCP
Message-ID: <1940@ncoast.UUCP>
Source record: 117937

I recently wanted to get a memory upgrade for my 130xe to give my
Kyan Pascal some more breathing room... the first thing that seemed to
be popular was the 320K ramdisk upgrade for the 130xe that a local
dealer was doing for $99, but when I went in to him, he recommended
something that makes more sense to me... the ICD MIO board which comes
in 256k or 1Meg ramdisk/printer spooler configurations and it can
replace your 850 interface... it also has an SCSI/SASI hard disk port...

With ICD's SpartaDOS (file time/date stamping, subdirectories, batch files,
etc.), the MIO is heaven... (I also bought their USDoubler which speeds
up your 1050 and doubles its density all the while letting you read and
write DOS 2.0 format, and read DOS 2.5... SpartaDOS automatically switches
density... some of you may also know that SpartaDOS also supports all
variety of disk drives for the Atari, including double sided drives.)

In addition to the above, the MIO also gives you complete and instant
control of your disk drive/ramdisk devices... you can instantly switch
the MIO ramdisk to be drive #1 and your 1050 set as drive #1 to be
drive #2 (that is, respond as device D2:). You can also leave the MIO
turned on when you turn off your machine, and boot from it almost
instantly... The guy who recommended this upgrade made a very good point,
if anything ever goes wrong with your 130xe, you can just replace it in
this configuration, whereas, if you make some hard wired memory expansion
to your 130xe, and something goes wrong with it, you are stuck.

This is very good stuff, in my opinion...

SpartaDOS with the USDoubler is about $60,
256k MIO board is about $200...

replacing the chips in the 1050 with the ones that come with
the USDoubler package is a minor hassle, so unless you are
fairly experienced at hacking hardware, I would recommend that
you have your dealer install the new chips.

134. Re: Questions on Turbo Basic Compiler (uudecode...)

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-25 23:50:40 UTC
From: btb@ncoast.UUCP
Message-ID: <1941@ncoast.UUCP>
Source record: 117938

When you all talk about uudecode, do you mean the hexbin/binhex programs
that were posted recently? Or is there a genuine uudecode for the Atari's,
or is that exactly what uuencode/decode is?

Turbo Basic won't work with SpartaDOS, because both SpartaDOS, and
Turbo BASIC use the same trick to get extra memory, they squeeze into the
OS address space on the XE/XL machines... this is a shame, but not the
end of the world... the version of Turbo BASIC that came across on our
local BBs included an autorun.sys file to automatically copy the
compiler, interpreter, and runtime driver to the Ramdisk, so in a sense
they "make use" of the 130xe's extra memory...

139. Controlling a robot with an 800...

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-26 17:39:50 UTC
From: jhs@MITRE-BEDFORD.ARPA.UUCP
Message-ID: <8701261739.AA17227@mitre-bedford.ARPA>
Source record: 117943

I would suggest that you consider using the joystick ports to output commands to the robot as an alternative. I think on an 800 $D301 controls the 3rd and 4th joystick outputs, which have 4 bits of output each.

On the 850 interface, you are talking over the serial bus, so it is not just a question of POKEing into an address. I think you can send commands by pretending it is the P: device (parallel printer) that you are talking to. However, you may have some trouble with its wanting to buffer up a whole line of data at a time. You may have to be careful how you OPEN the channel to the P: device. You should read up on the XIO command and read the 850 user manual carefully.

Using the joystick ports 3 and 4 you are talking to a PIA so it is a true parallel output situation. You will not have to worry about any "helpful" buffering of the commands you send out. Also, this will leave the P: port free to run a Centronics-type printer if you so desire.

Good luck.

To: <INFO-ATARI8@SCORE.STANFORD.EDU>
From: "GENE MERRITT" <F1.GDM@ISUMVS.BITNET>
Subject: Help needed for XM301

I would like to find a PD terminal program in BASIC that I could play with. I have an XM301 modem and I have had no luck using most BASIC programs because they require an 850-based or 835/1030 modem. I am now using 1030Express and I love it! But it is not compatible with my new Omniview 256. Omniterm (which came with my O-256) will not work with my XM301.

I would like to also get a copy of a BBS program (like AMIS) that also works with my XM301.

I have so many versions of Amodem and R:handlers (and appended versions) that I can no longer distinguish between them. I am one of the first people in my Users Group that got an XM301 so I am breaking new ground....

I would like to trade disks with someone who can help me out.

Thanks

Strictly speaking, your XM301 is not incompatible with OMNIVIEW256 per se, nor with OmniCom, but rather you may need a different RS-232 handler than the one you are using.

I am sure David Young (owner of CDY and author of OMNIVIEW and OmniCom) will be most willing to help you in finding a solution.

142. Re: ABRA-CA-DABRA

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-27 14:38:33 UTC
From: jhs@MITRE-BEDFORD.ARPA.UUCP
Message-ID: <8701271438.AA14127@mitre-bedford.ARPA>
Source record: 117946

The correct first line is:

```
begin 644 magic.tur
M 68!9P&_ N0]]SU/J%)!24ZD1DE,1:1"4D6H05)4J$U,I$=20:3!54Y/
```

The only (!) difference I can see is that the space character " " in the correct version has been turned into "`" (accent grave?) in your version. It might be interesting to compare the bit patterns. If you do a translation using unix "tr" to make ` into space, you might be all right.

Uuencode is a simple translation to understand, though not easy to implement in ordinary BASIC. (It should be relatively easy in Turbo BASIC, though!) What it does is to take groups of 3 bytes, or 24 bits total, and re-group them as 4 groups of 6 bits each (still 24 bits). These 6-bit groups are then expanded into 8-bit bytes by adding 32 (decimal) so the bytes have values in the range 32 through 95.

The bytes so formed are grouped into lines, traditionally with 60 or fewer bytes per line. Because of the 3-to-4 expansion, each such line corresponds to 45 bytes of packed binary input. One more byte is inserted at the beginning of each uuencoded line. This byte tells the decoder how many bytes of output will result from uudecoding that line. Normally that is 45 bytes. This number is also transformed by adding 32 (decimal) so it will be a printing ASCII character. Adding 32 to the normal value of 45 gives 77, which is an ASCII capital "M". Thus the first character of most uuencoded lines is "M", as you may have noticed.

The last line of the file is usually not precisely filled, i.e., only if the total number of bytes to be encoded in the input file is divisible by 45. So most of the time, the last line is shorter than 60 output bytes and the first character is something less than 77, or a character which comes before "M" in the ASCII "collating sequence".

Uuencode then inserts a single line with zero bytes converted. The byte count character is a space, which is ASCII 32 (decimal), or zero after subtracting 32.

Finally, a line containing the word "end" (3 characters) is tacked on.

I should also mention that the FIRST line of the uuencoded output file starts with the word "begin", then a space, then the unix protection code to be put on the output file, and finally the name to be given to the output file. This enables the uudecoder on a unix system to name the file correctly and set its protection code correctly.

Interpreting uuencode/decode on an Atari, it would be useful to translate unix protection codes in some way so that the output file is locked if the

unix code specifies read only, but my uudecoder isn't so fancy. Also, it would be useful to name the output file from the name given in the first line of the uuencoded file if no other name is given at run time. Maybe in the final version...

I hope this is of help.

Source record: 117947

Yes, there really is a uudecode for the Atari... although some people have
been having trouble with it. I think the problem may have been with
end-of-line characters. Make sure that the uuencoded file contains ATASCII
end-of-line characters (hex $9B) and not ordinary ASCII ones. The translation
usually takes place when uploading from an Atari to another system. Most
Atari downloading programs can translate back into ATASCII for you.

Perhaps when I write my final version (also including uuENcode) I will try to
make it fix up things like EOL characters.

re: "When you all talk about uudecode, do you mean the hexbin/binhex programs
that were posted recently?"

for those of you who haven't been keeping up on your reading:

There are two alternative methods of transmitting binaries over the net that have been under discussion over the past weeks:

BINHEX/HEXBIN are Atari Basic programs that convert binary files to text files containing 2 hexadecimal characters per byte. The file format is unique to these two programs. Author: Fleysher.wbst@Xerox.COM

UUDECODE is an Atari Basic program with machine language assist which decodes a more efficient representation of binary files than the hex files described above. Unix machines use this more efficient file format. Author: jhs@mitre-bedford.ARPA

Subject: eprom burner

I would love to build an eprom programmer...I started on the one in the
Dec.85 ANTIC but I never got it off the ground. Is this the one that you built?
I have yet to find someone who has built it. Do you have any suggestions for
construction? Could I get a copy of your plans(if they are different)?

I would like to etch a PC so that I don't have to hand-wire everything.

147. Testing for BASIC enabled or not...help!

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-28 04:51:55 UTC
From: jhs@MITRE-BEDFORD.ARPA.UUCP
Message-ID: <8701280451.AA06862@mitre-bedford.ARPA>
Source record: 117951

Several users of my Atari 8-bit uudecode program have reported problems with the output file not containing any data despite the fact that the program otherwise seems to run correctly.

I now believe that the problem is caused by my using an incorrect test for whether or not BASIC is present, inside the machine language subroutine. The test I used is to check location $6 and take a nonzero value there to mean BASIC Not Enabled (BNE!). I am either going slowly bonkers or else I somewhere found information to the effect that this was a reasonable thing to do. Since it worked on my 800XL, I stopped trying to fix it until people started complaining.

Now I see that Mapping The Atari seems to feel that location $6 should be a 1 if and only if BASIC **IS** enabled. Clearly that is inconsistent with what I thought was true and so my subroutine would interpret the 1 to mean that it is being called without BASIC. It would therefore refrain from updating the Current Length parameter, and Voila!, OBUF$ would appear to have whatever current length value was last set by somebody who knew what they were doing. (Not me, obviously.)

Since my own 800XL seems to disagree with this interpretation, it seems that reversing the logic of my current test is not the right thing to do. (However, this might solve the problem for you 800 owners.)

Does anybody out there in Net-landt know what is the RIGHT way to test for the presence of BASIC?

Failing that, of course I could patch the subroutine to simply ASSUME that it should set the current length parameter. This would affect only users of the subroutine who wanted to call it directly from assembly language, but clearly this patch would work for all users who merely took my BASIC program and used it.

Any suggestions?

-John Sangster

148. Another try at uudecode for the 800...

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-28 06:54:40 UTC
From: jhs@MITRE-BEDFORD.ARPA.UUCP
Message-ID: <8701280654.AA08218@mitre-bedford.ARPA>
Source record: 117952

I have made a change in the BASIC uudecode machine language program which I hope will make it work correctly on both the 800 and the 800XL, including OMNIVIEW-equipped 800XLs. (Fingers crossed...) The revised program is attached. I would appreciate confirmation from those who have had trouble running uudecode on their 800s, that this version DOES work. (If it does.)

Note that the attached file has normal ASCII line feeds (or whatever) instead of ATASCII EOL characters. This means that it prints normally on non-Atari systems and can be transmitted in 7-bit ASCII mode. BE SURE when you download it to use a mode which translates it back into ATASCII so you will get ATASCII End Of Line (EOL) characters back.

Good luck. Let me know if it now decodes Turrible BASIC correctly.
I will re-post Turrible BASIC in uuencoded form so you will be able to test it.

Thanks for the explanation of how UUDECODE works. I'll give the new version you distributed a try as soon as I can.

I think you should ALWAYS assume you have to update the length parameter of OBUF$ - i.e., the ML DATA statements in you BASIC program aren't being executed unless the user is really in BASIC. Different versions of your routine for non-basic users is an option. However I also think it's a mistake to be depending upon BASIC's data structures at all. The ML in your DATA statements would be more bullet proof if you allowed BASIC to set the length of OBUF$ based upon the return value M from the ML routine.

re: the line feed problem: When uploading to your UNIX environment you must specify straight ATASCII to make sure no translation occurs to screw up the (binary) data. Also note that the line feeds do not look like line feeds in their UUENCODED state, so selection of ATASCII vs. ASCII on download from UNIX to the recipient's Atari should not make any difference in the UUENCODED data - only the terminator character at the end of each line of 60 bytes. Is your ML routine sensitive to this terminator character?

Dan

The ML routine pays no attention to the terminator character, but the BASIC calling program is supposed to read lines and pass them to the ML routine. If the terminator character is wrong, BASIC will never see an EOL so will think the whole file is one long line.

As for the calling program setting the buffer length, the user is free to use M as he/she sees fit, but I was trying to minimize the non-ML overhead in the calling program. I **HOPE** your concerns are unfounded, now that I have gotten the logic of detecting BASIC present working right. The variable locations I used are well documented and should be fairly (!) standard in all software that attempts to be compatible with Atari BASIC.

If you replace the POKE 6,1 in line 102 with POKE 1,0, that should convince the subroutine that BASIC is not enabled, so it won't meddle with the length parameter. You might also try just removing this line, as it should not be necessary. It appears to be needed when running OMNIVIEW and switching BASIC ina and out with a program I got from COMPUTE! awhile ago, but it probably is not needed by most users.

From: btb@ncoast.UUCP
Message-ID: <1959@ncoast.UUCP>
Source record: 117856

I have d/l'd the hexbin and binhex programs, and they work, but, as we all know, they are very slow, and the binhex process doubles the size of your file for transmitting...

The uudecode program has apparently been causing some problems, too... I have d/l'd it, but I haven't tried it yet...

I would like to propose that if somebody would post the uudecode algorithms, I will write uudecode/encode in Deep Blue C... binhex it to the net, so everyone can get it... this way at least it will be fairly fast, and I could also make the DBC source available for others to monkey with...

Please send the algorithm description to me... Thanks.

>to the robot as an alternative. I think on an 800 $D301 controls the 3rd and
>4th joystick outputs, which have 4 bits of output each.

Yes and no A bette choice and the one I used is to control the robot out
of port 1 via joystick, and port two for line to the robot. Its been about
three years since I worked for Atari, on robots - yes they were planing to
release one for 129 +- and it had a remote control. You could
pick up a set of atari remote control, throw tinfoil around the case and they
will work great for interfacing to the robot. With one joystick port you can
set up the use of 4 motors plus foward and reverse. I used a resistor, then
a 2n3904 transisor then a 12 volt relay to control the motor , You could use
a 555 - 556 timmer instead of the relay. If you ave any other questions just
reply to me I could dig up a circuit if you really need one. I did work
with the person who posted articles in antic a while ago(about 2 years)
If you are having doubts about what language to use then try to use PNS forth
it is perfect language for robots.

I am also still having problems getting the compiler and runtime system working. I would appreciate a copy of these also. From the arpanet I can ftp an object module. From elsewhere, either binhex or uuencoded formats would be acceptable.

I have a working version of the interpreter and all documentation that is available. (So far as I know.)

Incidentally, I have found that the interpreter has some problems with floating-point operations when run under OMNIVIEW. Everything else I have tried seems to work fine with OMNIVIEW. I am hoping that the FP problem can be corrected easily within the interpreter. I don't know if the same problem will affect the other modules.

Source record: 117859

I recently saw a drawing-type tablet device for inputting sketches to a home computer. It had a drawing surface and mounted on it was a two-piece arm hinged at the 'shoulder' and 'elbow'. At the 'wrist' was a stylus which you used to trace your sketch. It was available for 8-bit Ataris and Texas Instruments home computers. The Atari version came with software contained in a plug-in cartridge (ROM), so you didn't even need a disk drive! The department store selling it seemed to be trying to get rid of them and the price was about $25. I suspect the 2 'hinges' may have been connected to pots (potentiometers - rotary variable resistors) that fed into the Atari's paddle (joystick) inputs. The software then computed the x,y coordinates of the stylus from the angular rotation of the 'hinges' and the lengths of each arm. This would let you draw a freehand line drawing, and then by using the stylus as a pointer to a menu, perhaps color it. The store is not near my home so I'm not able to go back and get the name of the device and its manufacturer.

Brad:

Attached is the uuencode/decode definition and a c program for it.

I have fixed the uudecode that I posted so I think it now will work correctly.
This version is in BASIC, so even those who don't have a c compiler can use
it. Also, the inner workings are in machine language, so it is already fairly
fast, possibly faster than your c version will be.

I am (slowly) working on a version which does encoding as well. It may be
a couple of months until I finish it, though, at the present rate of
distractions.

Uuencoding has its problems. Some of the characters in the character set get
changed by some hosts. Lines ending in blanks sometimes get shortened in
transit. I have a file of reports of such problems which you should probably
read if you are serious about doing another version.

-John Sangster
jhs@mitre-bedford.arpa

----------------i-n-f-o---o-n---u-u-e-n-c-o-d-e-/-d-e-c-o-d-e----------------
From: randy@NLM-VAX.arpa (Rand Huntzinger)
Organization: National Library of Medicine, Bethesda, Md

Uudecode reads a file of the following format:

header line(1)->begin <mode> <filename>
data lines(many)-><length> <data>
trailer line(1)->end

where:
The header line fields contain:

<mode> is a three digit number specifying a Unix file mode (specifies
who can read and write the file. You can ignore this on a
non-Unix machine.

<filename> is the name of the file encoded below. You can use this
if it is compatable with file names on your system.

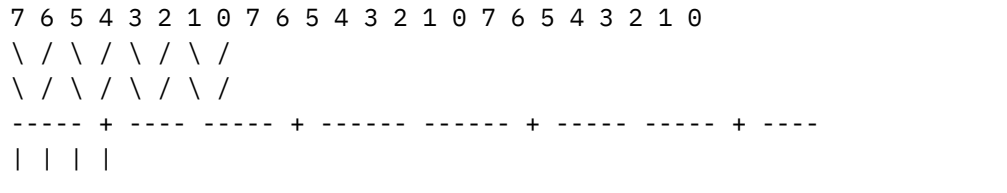
The data lines contain:

<length> is one character generated by adding the number of bytes
encoded on this line to 32 (ASCII space).

<data> is the <length>-32 bytes of binary data encoded into text
to produce 4 bytes of text for every 3 bytes of binary

data as follows:

Input: Byte 1 Byte 2 Byte 3



Output: Byte 1 Byte 2 Byte 3 Byte 4

In other words, encoding involves taking 3 bytes, breaking it
into 4 six bit chunks, adding 32 to each six bit value to make
it an ascii character, and output them.

To decode, you reverse this. Strip the parity bit, subtract
32 from each byte and repack into three words by shifting and
or'ing the pieces. I don't think I'll spell this out, since
it is an obvious reversal of the above steps.

The last line in the section simply says 'end'.

The file may contain junk before the begin statement and after the end
statement. So the decoder usually skips until it sees begin, extracts
the file name and decodes until it sees the end line. Be sure when you
implement it that you use the length byte to determine the length of the
decoded text, since stuff going though news sometimes gets padding added
to the text. Also, you need to do this is you want to get the file
length correct.

I've included a posted uudecode source for the Atari 520 ST below. I've
never used it, but it does give you something to look at. I don't know
whether you read C, but it might still be of help. There is nothing which
says it's copyrighted, so I assume it's public domain. If not, the
copyright was removed before I saw it. Some of the cruft in it indicates
it was originally written for Unix. I seem to have lost the credits on
this one, I don't see who posted it.

Source record: 117861

Here are some of the comments I have collected on uuencode/decode problems.
Many of them come from the atari16 news group, which is actively using
uuencoding/decoding. I have ended the file with a "wish list" for what
a uuencode/decode program should ideally do. Comments are solicited --
If somebody is going to write a really GOOD uuencode/decode package, it
might as well handle all known problems in the best way we can think of.

-John S.

From: Mike Vederman <ACS19%UHUPVM1.BITNET@WISCVM.WISC.EDU>
Subject: finally, i've figured uudecode ...
To: ST Users <INFO-ATARI16@SU-SCORE.ARPA>

After many, many problems with BITNET, IBM machines and uudecode, I have
found the true answer to having all of my files uudecode. Every single file
which has bombed in the past, now decodes perfectly.

The normal sequence that I do is to send the file over from the IBM machine
(actually we have an AS/9000N) to the AT&T 3B20 and uudecode on the 3B20.
Previously, the only two files which worked were UNITERM and uEmacs.

Now, however, I have found the solution, but I am uncertain as to the exact
cause. Here is what I do. First, while in Xedit, I set the logical record
length to 61, then I set the record format to fixed. The following commands
do this:

```
set lrecl 61
set recfm f
```

now, when I send the file to the 3B20, I enter the command:

```
sf file uue to acs19 at uhnix1
```

to receive on the 3B20, I enter the command:

```
receive $job/pnch6 >file.uue
```

(since the 3B20 is hooked up as a punch machine (yuck). What you do may be
different, but I know setting the logical record length and the record format
have made all of my files work.)
When I get to the 3B20, I do have to fix the file a little bit. I go to the
last line and delete the blanks to end of line, after 'end'. Then I go up one
line and make sure that there is only 1 (one) blank on the second to the last
line. Then I save the file and uudecode it. All the files I have tried thus
far have worked, and most of these have always bombed.

Mike

From: <MHD@slacvm.bitnet>
Reply-To: MHD%SLACVM.BITNET@forsythe.stanford.edu

Like others, I had little success at first in decoding the uuencoded files on this net. After looking closely at the files I noticed that the tilde character (~) was present when it should not have been. Upon further inspection I found that the carat character (^) was missing in all files. I tried a global change of tilde to carat and had no further trouble

Perhaps many others have been screwed up in the same way by IBM machines in the net. Perhaps at other sites just one other character is screwed up. Give it a try, preferably do it first on a .ARC file where deARCing will show errors on the CRC checks.

The only characters that should be in the uuencoded files are: space( ) through underline(_), ascii 20 through 5F. All of these should be present in a file of reasonable length.

Note: The tilde and carat may get screwed up in this file. They are ascii 7E and 5E respectivly.

From: XBR1Y049%DDATHD21.BITNET@WISCVM.WISC.EDU (Stephan Leicht c/o HRZ TH Darmstadt, Germany)
Subject: UUDECODE difficulties / Translation tables

I found my troubles in being not able to run some uuencoded programs comming over the net.

The translation of the not-Char/circumflex(^)-Char is not unique.

Translating it to EBCDIC 5Fhex and sending it over some gateways, it not always returns as EBCDIC 5Fhex, sometimes it returns as EBCDIC 71hex. (I saw it sending it to ucbvax and return)
Now I have told our translation table to recognize 71hex as 5Fhex too.

Strange !

Maybe that this is a hint for those having no success in uudecoding.

From: mcvax!ukc!dcl-cs!bath63!pes@seismo.css.gov (Paul Smee)
Organization: Bath University, England
Subject: Re: Lattice C and UUDECODE

I've found several problems with uudecode, which are caused by the uuencoded file being munged by 'terminal handlers' enroute to me.

The symptoms sound like some I've seen complained about, specifically
that the file appears to decode, but bombs. On looking at the files,
I found 2 different sorts of problem.

First, spurious 'control chars' get inserted in some cases. In fact,
these appear to always be NULs (0x0) put in as 'delay padding' by
someones term handling software.

Second, trailing spaces get stripped.

It is fairly trivial to modify uudecode to ignore all control chars
(less that ASCII space) -- and harmless, as they should not be in
a uuencoded file. Then, pad the line out to an arbitrarily large length
using spaces (I simply tack 64 spaces on the end, in my buffer, before
decoding a line). Appending 64 spaces is crude and inelegant, I know, but
it insures that there will be enough in all circumstances, and is a much
simpler mod than actually looking to see how many are needed -- especially
since the line may contain as yet unprocessed control chars to be thrown away.

Since making these trivial changes I've had no problems with uudecoded files.

Hope this helps someone...

From: <RDROYA01%ULKYVX.BITNET@WISCVM.WISC.EDU> (Robert
Royar)
Organization: University of Louisville
Subject: Another version of uue/decode offered (repost)

I have a version of uue/decode that I have been testing and that seems
to avoid some of the problems with the present setup. I added some
code to the original programs to do some error checking. The format
of the files the encoder uses is similar to the current version. If
you have the current version, you can delete the extra information
with your word processor. My version adds the following things:

1. It breaks up long files so that each uuencoded file is no
more than 300 lines long.

2. It places and include directive at the end of each file at
the break so the companion program can reassemble the files
into a program.

3. It adds a key table at the beginning of each file so that
the decoder can index into this table to find the value for
letters in the file. I discovered that the errors I had with
uudecode were often because a mailer had changed each instance
of a character to something else. This solves that problem.

4. It checks the key table for integrity before it decodes the
file. This way if both 'H' and 'Z' have been changed to ' ',
it will exit and tell you.

5. If it finds a letter in the file that was not in the key
table, it issues a warning telling what the character was,

the filename, and the current file position.

6. It appends a 'part' letter (a-z) at the end of each output
line to avoid truncation problems.

This program makes uue/decoding somewhat simpler than it has been
because it breaks the files up into parts automatically and
reassembles them. It actually is smaller and runs faster than the net
version of the program because I used freopen() to cut down on file
pointers and I used register variables where possible. If you are
interested in this program, drop me a line and I will post it to you.

Robert Royar
rdroya01@ulkyvx.bitnet
<NOTE (jhs) - This program runs on the ST and would need work to port to
the XL/XE/800 series.>

Summary of desirable uudecode features (J. Sangster 30 Jan 1986):

1. Should check for characters outside the range $20 to $5F, which are
not legal uuencode output and indicate a corrupted file.

2. If found, $7E (~) should be changed to $5E (^).

3. If found, $71 should be changed to $5F (acc. to Stefan Leicht)

4. The decoder should be insensitive to loss of trailing blanks at the
end of a line. I.e. if the line is shorter than the indicated number
of bytes (determined from the first character M or whatever), it should
assume that any missing characters were blanks, $20, which will
uudecode to nulls ($00) after subtracting $20.

5. If any nulls ($00) are found in the uuencoded file, they should be
deleted before processing.

6. The encoder should never generate files longer than some maximum
size. One person suggested 300 lines. I think 32K is acceptable
to most mailers but room should be left for comments at the top.

7. The decoder should reassemble the parts of a file automatically if
it was broken into pieces.

8. The decoder should ignore comments before the begin line and after
the end line.

9. The "translation table" idea -- inserting a list of all possible
legal characters and checking what is received for uniqueness --
is a terrific idea!

10. Since unix systems name the decoded output file from the info in the
begin line, and also set protection codes from it, we Atarians should
adopt some conventions related to these procedures. I suggest:

(i) If the protect code is is less than 700, lock the output file.
(On a unix system, the first digit is owner rights and 7 is

"all rights" so this convention makes you think if the owner
is not supposed to have all rights.)

(ii) The decoder should display the filename embedded in the file
and ask if it is OK. User can enter a <RETURN> to accept it
or a new filename if desired.

11. While we are at it, it would be nice to be able to handle sector encoding
and reconstruction of whole disks.

That's all I can think of. Anybody have any additional ideas?

-John S.

158. 800XL with sick ROM - Help!

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-30 20:00:49 UTC
From: kdj@teddy.UUCP
Message-ID: <3727@teddy.UUCP>
Source record: 117862

My 800XL ROM is sick. The memory test on the ATARI shows the left hand bar in red (meaning that the ROM is bad). Does anyone know of a quick (and cheap) way of replacing the ROM. Can I burn a new one ? Can an ATARI ROM be purchased at a reasonable price ? I have the ability to replace the ROM myself - I just need a new one.

Your help would be appreciated.

Thanks

ps: I purchased the 800XL a few years back (when it was still quite expensive) so I'd rather not just buy a new 800XL.

I don't know how to interface the 850 port to the robot, but you could skip the 850 and drive the robot directly (or via an inverter/buffer - SN7406? SN7407?) from the 800's joystick ports. They are driven by (if I remember correctly) 2 6520 PIAs, so ports 0 and 1 provide 8 individually controllable bits of control, and ports 2 and 3 provide 8 more. A total of 16 bits which can individually be set to be either inputs or outputs.

160. BINHEX of TBASIC interpreter with HEXBIN.LST

Newsgroup: comp.sys.atari.8bit
Date: 1987-01-31 19:09:06 UTC
From: btb@ncoast.UUCP
Message-ID: <1979@ncoast.UUCP>
Source record: 117864
Body handling: HTML body converted to readable text

Hello folks.

Below, I've included everything you need to get started with
Turbo BASIC... first, there is the listing of Dan Fleysher's HEXBIN.BAS
program, and second, there is the Turbo BASIC interpreter which has been
BINHEX'd using Dan's BINHEX.BAS.

Binhex is nice, because it is a simple enough idea that most of us
could write a program to encode and decode in a fix... and a simple idea
means less chance for bugs... jhs's uudecode is also something that we
need, because it has a 3 to 4 expansion ratio compared to binhex's
1 to 2 ratio..., but with its increased complexity it is more challenging
to write a bug free program to handle its protocol, so while some of us
are working to develop good programs to uuencode and uudecode, the rest of
yyou are without Turbo BASIC, which I think is one of the most important
programs to come out for the Atari 8-bits since the Express terminal
programs... additionally, Turbo BASIC would be a much more productive
place to write more sophisticated programs like uudecode & and uuencode...
(but without Turbo BASIC, obviously, those that don't have it couldn't
use such programs, so here it is!).

It took approximately 10 minutes to binhex the interpreter, which
we will call TBASIC.COM, from ramdisk, to ramdisk... a couple of points:

1) Turbo BASIC will not work under SpartaDOS 3.2... both TB, and
SpartaDOS 3.2 try to hide in the same address space as the OS,

2) Turbo BASIC will only work with XL/XE machines, because these
machines have RAM which can be switched into the OS address
space, and this is how Turbo BASIC finds its place to hide...

Regarding TB Docs, perhaps some other kind soul will u/l them...
there are lots of new commands in TB, and it is probably about 95%
compatible with your existing Atari BASIC programs, so you can use
Turbo BASIC to speed them up: WARNING: There have been problems with
people trying to use terminal programs like Amodem, etc., in TB...
Apparently, TB uses the space normally used by the R: handlers, but this
is a minor shortcoming when you consider everything else that TB has.

The TB package that I have gotten off of local BBs here has
included two 80K shrink files with the interpreter, a compiler, a
runtime package, some neat demo programs, and all the docs, but this
should get you started, and once you have TB, you could use programs
(eh, jhs & Dan?) written in TB to do uuencoding and decoding, so
potentially, we could post the whole package at some point...

What to do:
save this message to a file
edit out the TBASIC.BHX and HEXBIN.LST files
d/l them to your machine... I recommend some
form of Kermit for this, like Chameleon, because it
will automatically convert your machines EOLs to
ATASCII EOLs (155 dec)...
HEXBIN it! and enjoy!

Brad Banko

162. Music demo program

Newsgroup: comp.sys.atari.8bit
Date: 1987-02-01 21:32:39 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8702012132.AA14433@mitre-bedford.ARPA>
Source record: 117866

Here is a silly little program that plays random music on the Atari 8-bit computers. It demonstrates some principles of music theory, such as the use of the twelfth root of two as the ratio between halftones in the "tempered diatonic scale". The algorithm picks a random step up or down from the current "base note", then picks some other more or less harmonious notes to go with the base note and make a chord. The result is (to my ears) usually pleasing, sometimes a little dissonant -- but then so are a lot of modern pieces of so-called music. There is also a bit of logic to vary the tempo occasionally by holding a note two or perhaps four times as long as the minimum.

You can probably learn from the basic program and make interesting modifications on your own. Enjoy, or ignore, as the case may be.

If you have uudecode on your host system you can uudecode this file there and then download it to your Atari. You should use 8-bit transfer mode as the uudecoded file will contain ATASCII characters such as end of line, and is a tokenized BASIC (not .LST) file.

If you don't have uudecode on your host, you can download this file as a normal ASCII file, letting your terminal emulator translate into ATASCII and then use the uudecode I posted on the net to decode it on your Atari. If anyone lacks the uudecode program, I can post it again.

164. uudecode revision..

Newsgroup: comp.sys.atari.8bit
Date: 1987-02-01 23:37:48 UTC
From: jhs@MITRE-BEDFORD.ARPA.UUCP
Message-ID: <8702012337.AA15709@mitre-bedford.ARPA>
Source record: 117868

Here is a minor revision of uudecode. This version IS SUPPOSED to do the
following:

1. It should act like the latest former version in that it counts bytes
and hopefully works OK on 800s as well as 800XLs with or without
OMNIVIEW.

2. If you enter a RETURN for the output file name, it will proceed
until it has read the "begin" line of the input file. If it
finds a normal "begin" line, i.e. one with "begin" and something
ending with a space followed by a valid filename, it will use
that name for the output filename. Otherwise it will either
ask for a filename again or bomb, depending on its mood.

Note that this implies you can give it a nonstandard output file name
or let it use the one on the "begin" line by default.

By popular request, this version is also supposed to ignore header and
trailer comments, e.g. if the file is embedded in a mail message. It searches
for "begin" before even opening the output file.

Finally, the diagnostics at line 20 have been made a little more helpful.

I made this mod on the VAX and have not tested it on an Atari yet. But how
could such a simple change have any bugs in it? (Don't answer that!)
I would appreciate comments from my "Beta Test Site" users on whether the new
features work.

-John S.

Be sure to download with translation to ATASCII character set enable.
(The ASCII Line Feeds have to be translated to EOLs. $9B)

Source record: 117869

One note about this uu..code response...

The source I have for uu..code programs on a UNIX system where I go to school and on PC-clones written in Turbo Pascal is that when encoding, if a space (ASCII 32) is to be output to the coded file a grave (ASCII 96) IS inserted in its place. The reverse takes place running uudecode. Therefore I question that the correct version would have any spaces in it at all if the uu..code programs are supposed to be fully compatible with the UNIX originals.

hopefully in my general area. Why does Turbo{
Basic only work on the XL/XE's? Can anyone modify it?
>Does anyone even have my computer?
>Thanks a LOT,

There is a turbo basic version, specially made for the 'old' 800
and 400 computers. I have a version lying around somewhere, and will
see if I can find it. Apparently it is diiferent from the XL version
because of some memory usage.
If there is enoug intrest I will transport, and send it through the net.

171. Thanks for the "pad" info

Newsgroup: comp.sys.atari.8bit
Date: 1987-02-03 18:59:26 UTC
From: njd@ihlpm.UUCP
Message-ID: <875@ihlpm.UUCP>
Source record: 117875

Thanks to everyone who responded to my request for info on the Koala Pad/ Atari Touch Tablet. Randy Pacetti at AT&T-Network Software Center came through with his used Koala Pad w/software, which I bought from him, and am quite happy with. The Pad really does seem to be a nice input device; it certainly works well with Microillustrator. I hope to have time to program for it, someday - in the meantime, I need to adapt the graphics display/print program (for Microillustrator pictures) from Analog, for my "oddball" printer (Toshiba P1340). This should be interesting!

Cheers,

Nick (I love milking my 8-bits for all they're worth) DiMasi

There were questions about the format of these picture files.
Here it is (below). I also have an Action program that
reads and displays them.

Livermore, CA 94550 (415) 422-5444
UUCP: ..{ihnp4,qantel,ucdavis,pyramid,styx,topaz}!lll-lcc!langdon
..{gymble,ll-xn,seismo}!lll-crg!lll-lcc!langdon
------------------------------------------------------------------------
Picture Data Format
for
MicroIllustrator
and
Koala Painter
and
AtariArtist

Each file consists of two sections,
a header and the data.

Header:

Offset Description
------ ----------------------------
$00-03 ID sequence: $FF,$80,$C9,$C7
$04-05 # bytes in header (-1)
usually $1A,$00
$06 Revision #: $01
$07 Compression type: $00=none,
$01=vertival, $02=horizontal
$08 Graphics mode: xx00yyyy where
xx=GTIA bits from GPRIOR and
yyyy=ANTIC mode. Nprmally $0E
$09-0C Active screen area (L,R,T,B)
$00,$2B,$00,$C0
$0D-11 Color register data for
COLOR0 thru COLOR4
$12-13 Total length of file: lsb,msb
$14-15 Unused: $00,$00
$16-19 Reserved: $9B,$9B,$9B,$9B
$1A Unused: $A2
```

The data follows immediately. If uncompressed, then it is in screen RAM order.

In horizontal compression, the data will fill memory on order (fill each row on the screen left to right, top to bottom.

In vertical compression, The data fills a 1-byte column, every other row, followed by the skipped row, then on to the next column.

Compressed data consists of variable length records. The first byte of each record determines the type of record. Format:

```
1st byte 2nd byte 3rd byte
<--------><--------><--------><....>>
|0|Cnt<>0 | Data |
Cnt bytes of repeated Data
|1|Cnt<>0 | Unique | Data | ...
Cnt bytes of unique data
|0| 0 | msb Cnt | lsb Cnt | Data|
Cnt (>127) bytes of repeated data
|1| 0 | msb Cnt | lsb Cnt |data|..
Cnt (>127) bytes of unique data
```

The subroutine READPIC.MAC will read a picture file onto a mode E or F screen (assumed). It only looks at the compression type and color values in the header and assumes that the picture area and mode are compatible with a full screen mode E or F picture.

>My 800XL ROM is sick. The memory test on the ATARI shows the left hand
....

Well, there are a number of ways to approach this.

If you have access to a good ROM, an EPROM programmer, and 27128 EPROMs,
you could duplicate a good one. As far as I know, the 600XL, 800XL, 65XE
and 130XE all have the same ROM. If you have a friend with a broken machine
of any of these types, you could also try to use a ROM from it.
I have used a 27128 EPROM (either 200 or 250 ns, I don't remember), and
know that it works.

If this is not feasible, there are several places which sell Atari parts.
American TV and B&C Computervision come to mind. They advertise in
Antic and Analog, among others. I have not dealt with either, but I hear
that they promise delivery in the 4-6 week time frame.
Price should be around $10.

Finally Computer Mail Order (again, I have not dealt with them) recently
advertised 600XLs for $30 or $35. Since they are identical to 800XLs
except for the memory circuitry and the video output, you would get a great
supply of spare parts that way. Of course I don't know if they have any
left.

Before doing any of this I would try to swap parts with a good machine,
to be sure it really is the ROM and not some other part of the memory
circuitry which is causing the problem.

Source record: 117879

I am constructing a set of boards, along with some modifications, to allow an 800 to emulate a 256K Newell-enhanced 800XL or whatever. The questions I have are 1) what locations are switched in/out when RAM is substituted for the operating system/etc? I assume that the locations switched are $c000-$cfff and $d800-$ffff, but I am not certain what is mapped into $c000-$cfff if the OS is not deselected. The hardware at $d000-$d7ff is never switched out, correct? Secondly, the not-halt signal is not "easily" available to the slots in the 800. Would it make much difference if I simply set it up that one of the bits in $d301 switched an alternate bank of RAM in at $4000-$7fff (the one that means 'put processor on alternate bank') and let Antic fend for itself? This shouldn't be a problem for most programs, because Antic is usually somewhere up above $8000 anyhow. This would mean that Antic is on the alternate bank whenever the processor is. That might create some problems, so I may try to route the not-halt signal from the CPU board.

Alos, does anyone out there have much experience etching circuit boards? Or know where I can have some etched? I bought a starter kit from DATAK, but I don't know if I have the skill to draw this thing up as a photographic image. I think I could lay it out, as a general guideline, but the boards are going to have to be double sided, so I am wondering if there is somewhere I can send the plans and have the boards made for me. Along those lines, since I am planning on (sooner or later) making this into a set of boards (3, with an expansion port on one of them- I've already got some things to add there) is there any interest in the world of 800 owners for something like this? I may write up a paper, describing the necessary mods, etc.

Source record: 117880

I don't know how to do it, but you ought to be able to use any modem with
your 8 bit machine. I found out by accident that the 8-bit operating system
which is built into the machine (i.e., it's there even if you don't have a disk
drive)includes software for inputting and outputting data on the serial port.
It follows the standard custom of sending the bytes out one bit at a time on a
single pin. Incoming data is received on another pin of the serial port. Each
byte is preceded by a start bit, and is followed by a stop bit, and the data
bits are ordered least-significant-bit first, six more bits, most-significant
bit last. This is standard asynchronous serial transmission with 8 data bits,
one start bit, one stop bit, no parity. The baud rate is settable by pokeing
the appropriate memory locations, and setting up the serial port for
asynchronous I/O is also done by pokeing appropriate codes into the right
addresses. Sorry, I don't have the addresses or the values that must go into
them. These can be found in the hardware manual, or other published literature.You may have
to write your own software to configure the port and input and
output the data, unless your already have some program that interfaces with a
modem or does terminal emulation.
On the hardware side, the voltage levels used by the serial port are not
compatible with what a modem expects to see. The serial port operates at TTL
levels: logic 0 = zero volts, logic 1 = 5 volts. The modem expects RS-232
levels: logic 0 = +3 to +24 (I think) volts, logic 1 = -3 to -24 volts. You
must provide the hardware to do the voltage level translation. The easiest way
to do this is to use a chip such as the Maxim MAX232 which requires only 5 volts
and can be powered by the 5 v pin in the serial port itself. This chip
generates its own +9 and -9 volts for the RS232 levels and translates incoming
RS232 levels to TTL levels. Only a few external components need to be connected
to the chip (a few small capacitors and resistors) and the circuit is very
simple (see MAX232 data sheet).
I'm amazed at the number of features that were included in the original
8-bit machines that were not advertised or brought to the attention of
purchasers. Included at no additional expense were horizontal and vertical
smooth and coarse scrolling, animation by page flipping, custom display lists,
sprites, joystick ports that can be used for output as well as input, paddle
ports that can accept photocell and resistance thermometer inputs, tone
generation for dialing touch tone phones, asynchronous serial port for
communicating with modems or other (multivendor) computers. And all this stuff
was accessible through BASIC, worked with only 16kbits of memory, and didn't
require a disk drive or expansion box.

Actually, I think it is your uuencode which is not working correctly. There
should be a line with a byte count of zero (i.e. starting with either a
space or an accent grave) between the last line of text and the 'end' line.
While some uudecodes may not enforce this, all the uuencoded files I have
looked at contain that line.

subject: ATARI BASIC CART

I need some help. I recently moved and in the shuffle lost most of
my cartridges to my ATARI 800, the BASIC cartridge being among them.
I know the above sounds irresponsible, but I really do guard these
things carefully. Ironically these are the ONLY items I am missing as
a result of my moving.

I purchased my system (second hand) thru this usenet 3 years ago. I
have looked thru the YELLOW PAGES but find no mention of ATARI anything!
I called SEARS... they said they do deal in ATARI but said those cartridges
are not made anymore. I asked if they had BASIC on a disk and they said
I would have to write to ATARI? I looked thru some of my recent
COMPUTE! mags, but find no adds selling ATARI BASIC, though of course
there are adds selling other ATARI software. I will probably end up
writing to one of these if nothing else works, but I need BASIC now.

I have written a menu driven program in BASIC (! no flames please...its the
only language I know, and then just barely) to calculate personal income tax
bills that optimizes between forms EZ, 1040A, 1040, and Schedule D, and
lists any applicable credits that the user qualifies for. It also generates
MASS income tax form 1-2-3 from the info extracted from the Federal form.

This being the season and me with no BASIC cartridge.... in the words of
Ronnie Reagan "Well......"

Any helpful ideas would be appreciated. I'm also looking for info on how
to talk to a DEC LA-50 printer.

Dan Keeney

I think one of these is a valid path to me:

From: kdj@teddy.UUCP
Message-ID: <3737@teddy.UUCP>
Source record: 117885

I have seen a program (awhile back now) that could tell you the rotation speed of your disk drive. And given that you have access to a POT or some other adjustment screw, you could adjust and correct the speed. The disk speed, i believe, is slowing down and I am getting checksum errors on some of my use-to-work disks.

Does anyone know of (or have) a solution to this problem ? Your help would be appreciated.

The DEC LA-50 printer uses a serial port and seems to work the same as a crt terminal. By that I mean if you feed the printer the same bit stream that's going into your terminal, whatever appears on the screen will be printed on the paper. Also, if the sequence ctl-[(0 (with no spaces) to switch the terminal into its alternate character set are received by the printer, it too will switch to its alternate character set. (I'm not sure but this seems to be a vt-52 or vt-100 or ANSI standardized function). With the alternate character set you can draw neat boxes around (Capital letter) words, and draw horizontal, vertical lines, any of four corners, any of four tees, and crossing lines. This lets you produce organization charts and simple line drawings that are totally made up of ascii characters so that you can include them in electronic mail messages, and transfer files using text file transfer techniques without needing binary file transfer techniques. The only problem is that your computer may have different alternate character set than the vt-100? standard. To get back to the default character set, send the sequence ctl-[(B without any spaces between the characters, of course. (These sequences work on a vt-100 type terminal and LA-50 printer, they may be different for your terminal). Also, you may or may not need a null modem device at the printer if you feed it the same bit stream as your terminal.

I am new to the UNIX system and am also a neophyte Atari user. My system consists of a 130XE, a 1050 DD, and a 1030 modem. I would like some information in a number of areas:

1. Where can I get a VT100 terminal emulator program which will work with my system? Will this program control the modem also? Will it compensate for the 40 column format?

2. Is there an inexpensive way to upgrade this system to 80 columns? What programs are available which use the capability? How is the resolution?

3. Are there any public domain spreadsheets for this system? Where can I get them? Documentation would be a big plus.

4. I have downloaded programs from various BBS's (Compuserve, etc.) with mixed results. About half the programs load and run, the others do not. I am using the HomeTerm modem program. Is this typical?

5. My 1050 disk drive seems too make an inordinate amount of noise when switching tracks. Is this typical? Does documentation exist for this drive which would allow me to adjust/clean/repair it myself?

6. In general, what books/publications are available which would allow me to get more out of my system?

Thanks in advance for any help.

Steve Reinhold

187. Re: uuencoded uuencode for the 8-bits...

Newsgroup: comp.sys.atari.8bit
Date: 1987-02-06 22:00:26 UTC
From: jhs@MITRE-BEDFORD.ARPA.UUCP
Message-ID: <8702062200.AA00982@mitre-bedford.ARPA>
Source record: 117891

The difficulty that Brad has been having with my uudecode seems to be caused by the format of his uuencode output, which does not include the final line containing "zero bytes" to be uudecoded. VAX implementations of uuencode seem to include such a line. This comes out as a line containing just a single space before the <RETURN>. A space is $20 (or decimal 32) in ASCII, so a uudecoder subtracts $20 and gets a byte count of zero. If it is written correctly it decides that (a) there is nothing on that line to uudecode and (b) there are no more lines, either. The next line should contain "end".

I wrote the assembly language subroutine to determine that the byte count was zero and return without doing any decoding. It does however return a USR value of 0, which gets put into the M in my BASIC calling program in the line "M=USR(UUDADR)". The next line tests for M=0 as the end condition and returns control down below to the lines which handle finishing up and closing files.

In Atari BASIC, if you want high speed, you have to put the critical code right at the beginning, because every time you ask BASIC to GOTO a line number, it has to search through all the stored program steps until it finds a line with that number. If you are searching for a line right at the beginning, the search takes the least possible time. That is why I put the "main loop" at the front, with just one line ahead of it to make the program start up correctly on a RUN command.

I also used just the one test for a line with zero bytes in it as the end condition. I felt that this would be a fast test. If you want to, you can make it actually look for the "end" line instead by inserting the test "IF (OBUF$(1,3)="end" THEN GOTO ..." instead of or in addition to the test for M=0.

-John S.

>I am new to the UNIX system and am also a neophyte Atari user. My system
>consists of a 130XE, a 1050 DD, and a 1030 modem. I would like some
>information in a number of areas:

>1. Where can I get a VT100 terminal emulator program which will work with my
>system? Will this program control the modem also? Will it compensate for
>the 40 column format?
There are several VT100 emulators available. VT10SQ is a public-domain
program which displays 80 columns using the high resolution capabilities
of Graphics Mode 8 (320x192). It does only a partial emulation, e.g. not
handling graphics (line drawing) at all. It also does NOT include any
file transfer or data capture capabilities. Also, the keypad is accessed
by prefixing each keystroke with an ESC, which I found "got old fairly
fast". It is NOT what you could call convenient.

Another program called Chameleon can emulate a VT100, among other things.
I believe it makes you scroll around to see all 80 columns, however.
(I have never used it.)

The best VT100 emulator I have seen is CDY's OmniCom, which I am using
to compose this message using the Rand screen editor on my VAX at work.
This one DOES do the line-drawing graphics and also includes kermit and
xmodem. It, however, requires CDY's OMNIVIEW O/S replacement chip to work.
That is, however, well worth considering, because OMNIVIEW gives you
a built-in 80-column capability -- built into the Editor (E:) device.
Also, it comes with an 80-column word processor which is pretty powerful.

>2. Is there an inexpensive way to upgrade this system to 80 columns? What
>programs are available which use the capability? How is the resolution?
I guess I already answered this one, partly. Since OMNIVIEW replaces
the 40-column E: device with an 80-column one, any program that uses E:
in Graphics Mode 0 (just text) will work with it. Unfortunately, this
rules out a lot of programs that unnecessarily use some other modes just
for jazzy effects, but still a lot of things work. Ask CDY for answers on
specific programs. The resolution is good enough to use routinely for
day-to-day word processing, although nobody would say it is as good as that
of much more expensive computers which were designed for 80-column output
in the first place. I used OMNIVIEW and OmniWriter (the 80-col word
processor) on a black and white TV for quite awhile, and it was perfectly
useable. I now use a Magnavox amber monitor and it is even better.
In fact, DARN NEAR as good as some of the amber monitors I have seen
used with the IBM-PC. It can be used with color monitors too, but only
ones which provide a separate chroma input.

As for "inexpensive", since OMNIVIEW comes with an 80-column word processor
and costs only about what a lot of other, 40-column word processors are

selling for, I would say it is fairly inexpensive, especially if you have not yet bought a word processor. (Current list price of OMNIVIEW last I heard was $39.95).

Atari has been promising to bring out an alternative 80-column adaptor Real Soon Now for many months. I think it is waiting for FCC Part 15 certification or something. It is supposed to be priced around $60, but we will only know for sure when it is available. It will probably have more support from software vendors, eventually, than the CDY product, but then it will be SIGNIFICANTLY more expensive when you consider that it won't include a free word processor. Also, it will take up desk space and (yuk) yet another electrical outlet. It may have important additional capabilities, but I don't know the details. Perhaps Atari can give you more complete information.

>3. Are there any public domain spreadsheets for this system? Where can I get
>them? Documentation would be a big plus.
There was a Type-In spreadsheet program called SpeedCalc published in March, 1986 by COMPUTE! magazine. Not exactly Public Domain, but close. The granddaddy of all spreadsheets, VisiCalc, is available for around $20 these days. Several others exist too.

>4. I have downloaded programs from various BBS's (Compuserve, etc.) with
>mixed results. About half the programs load and run, the others do not. I am
>using the HomeTerm modem program. Is this typical?
It sounds worse than average if the problem is line noise. The best way to download is with a file transfer protocol like xmodem or kermit. These should ensure correct files if the implementation you have is any good at all. I don't know how well HomeTerm works but it should be fine.

The other thing you might be running into is that the programs were written for the older Atari machine, the 800. Some (many) such programs use illegal O/S calls "to improve performance" and don't run on the 130XE or for that matter the 800XL. To test this possibility, you should obtain the Atari "Translator Disk" and boot it first, then boot the questionable program. If it is an O/S compatibility problem, it will then run correctly (assuming you loaded it with BASIC enabled/disabled as appropriate, etc.). (The Translator Disk installs an 800-compatible O/S in RAM in the same address space as the ROM O/S normally sits.)

Incidentally, OMNIVIEW will allow you to run a lot of the programs that otherwise would require the "Translator Disk", since OMNIVIEW looks almost exactly like an 800 O/S to the application software.

>5. My 1050 disk drive seems too make an inordinate amount of noise when
>switching tracks. Is this typical? Does documentation exist for this drive
>which would allow me to adjust/clean/repair it myself?
A "Field Service Manual" is (or was) available from Atari. It is part number FD100330, dated October 1983. Let me know if you cannot obtain it from other sources and I will see if I can help.

>6. In general, what books/publications are available which would allow me to
>get more out of my system?
Your Atari Computer, by Lon Poole, et al, is a **MUST** even though it
is aimed at the older models. There are near-equivalents from SAMS and
Weber Systems, Inc., both worth having. Poole's book is an excellent
source for becoming a virtuoso at Atari BASIC.

For Assembly language, buy Mark Chasin's book, "Assembly Language
Programming for the Atari Computers". It is wonderfully well written
and will be equally good for beginners and assembly language experts
who just need help with I/O, graphics, and sound features of the Atari.

Mapping The Atari is a must for everybody who is serious. It is like
a dictionary / roadmap of O/S variables, BASIC tables, etc.

If you are REALLY serious, there is De Re Atari, the Atari hardware
manual, the O/S manual, the DOS manual, and Inside Atari DOS, by COMPUTE!
Magazine. Oh, yes, and The BASIC Source Book. These give details like
schematic diagrams, connector pinouts, and source listings!!!

Speaking of magazines, there are two main ones, ANALOG and ANTIC.
ANALOG is more technically oriented and ANTIC more toward games.
COMPUTE! Magazine always has a small number of articles of interest
to Atarians, some of them so good it would be a shame to miss them.
I try to look at every issue and buy it occasionally.

>Thanks in advance for any help.
That's what the Net is for! Last year at this time, I was mainly asking
questions myself!!!

>Steve Reinhold

------- End of Forwarded Message

Good luck getting started with your 130XE. These machines are so capable
that they seem to attract talented people. As a result there is an incredible
amount of good software available, both Public Domain and otherwise.
I am sure you will get a lot of mileage out of your 130XE as I have out of my
800XL.

-John Sangster / jhs@mitre-bedford.arpa

189. Re: MODEMS +

Newsgroup: comp.sys.atari.8bit

I can't help you with the Atari 1200 baud modem, but you might consider the Avatex 1200 as an alternative. I have been using one for many months now, and it has worked flawlessly. The only time I have ever seen character errors is when my wife picks up another extension by mistake. The Avatex is available for less than $80 from some sources and does autodial, autoanswer, autobaud. It follows the Hayes standard well enough that most programs will work with it. It has a bank of back-panel switches which let you set up the handshake signals like Data Terminal Ready (DTR) in hardware if your software doesn't know what to do. I have found this VERY useful for quickly identifying why a terminal emulator program doesn't work. And fixing it, too, without having to rewrite it or rewire the cable.

It does NOT have a built-in speaker, but DOES have a jack for connecting a phone to it (so you can listen to call progress on the phone if you wish).

190. ACTION! summary

Newsgroup: comp.sys.atari.8bit
Date: 1987-02-07 03:59:44 UTC
From: daryl@ihlpe.UUCP
Message-ID: <1513@ihlpe.UUCP>
Source record: 117894

Someone locally asked me for ACTION detail information. I ended up with
something detailed that I thought should be shared with the net.

Daryl Monge UUCP: ...!ihnp4!iheds!dlm
AT&T CIS: 72717,65
Bell Labs, Naperville, Ill AT&T 312-979-3603

****
****

ACTION! is an OSS super-cartridge. You get a text editor which is general
enough to use on any text file, a monitor for running programs, dumping
variables, etc, and the compiler itself (which is accessed from the monitor)
The big linkup between the compiler and the editor is going into the editor
immediately after a compiler error will place the cursor at the offending
line. Useful, since the compiler stops after ANY error (the only annoying
deficiency.)

EDITOR summary:
Insert/delete line/character with the normal keyboard keys for them
tab, set tab, clear tab, using normal keyboard keys
Forward/back screen
Find characters
Set/Goto tag
home/end of buffer
replace/insert mode (the editor is like gmacs - modeless)
paste deleted lines
read/write files
clear buffer
create/delete split screen windows -- can do 2 windows, a different
file in each.
Substitute string (no regular expressions)
undo last delete
shift window left/right. Useful when indenting becomes a problem on
a 40 column screen.

The MONITOR:
compile /edit/return to dos commands
Proceed from either a break key or library break() function
run a program
set a memory location (poke)
write a compiled program to disk
execute an immediate command (any one line meaningful to the compiler)
display a memory location (peek)
dump memory (bulk dump)
set system options:

display turn off display will compute bound. On
atari's this can improve compiler performance
30% or more.
bell on/off an audible bell on errors
case sensitive on/off
trace on/off, trace each subroutine call, not
including library functions.
list on/off list program while compiling
window 1 size size in lines of the top window when using
split screen mode
line size Max line size, must be <240
left margin Default of 2, can be 0 if you have a decent
TV or monitor.
EOL character The visible end of line character, useful if
you want to know if the file has lines with
trailing blanks.

Of course you really want to language details, since the above is really
sugar for the development environment.

identifiers are arbitrary length, must start with an alphabetic, and the
remainder must be alphanumeric or underline (_)

Constants are
digits decimal
$digits hex
'letter a single character constant
"string" a character string. ACTION! strings are
[1 byte count]characters

Fundamental Data types: (by the way - all ACTION! variables are static)
BYTE obvious. CHAR is treated the same
CARD 16 bit unsigned
INT 16 bit signed
POINTER to any of the above

Variable declarations:
BYTE name1,name2 simple storage allocation
BYTE x=[1] initialization
BYTE y=$8000 declares y as residing at memory loc $8000

Expressions (in priority):
- unary minus
* mult
/ divide
MOD remainder
+ add
- binary subtract
(= is not an operator in ACTION!, hence z=(x=y) is not legal)

Bit wise:
& and
% or
! xor
XOR same as !
LSH logical (vs arithmetic) left shift
RSH logical right shift

relational:
= equality
inequality
<> same as #
> >= < <= obvious
AND logical and, not the same as &
OR logical or, not the same as %

expressions are cast in the order of BYTE->INT->CARD

Assignment:
= simple assign
==<operator>
where <operator> is any binary operator, including LSH, RSH
etc., just like += in C.

Statements:
IF THEN ELSE FI
IF THEN ELSEIF THEN ELSEIF THEN ... FI
DO <loop> OD
FOR TO STEP DO <loop> OD
WHILE DO <loop> OD
DO <loop> UNTIL OD
There is no case and no GOTO in ACTION!!!!!!!

Functions and subroutines:
They are separated as in Fortrash.

PROC name(BYTE arguments INT arguments ...)
FUNC name(...)

and most interesting

PROC name=<address>(arguments)

where address is an address in memory. Makes it real easy to call OS
routines in ROM, etc directly from action without any assembler language
non-sense.

There is a RETURN statement. IT IS THE ONLY WAY TO KNOW WHERE THE END OF A
ROUTINE IS!! It is a simple minded compiler and probably only generates a
RTS instruction when it encounters a RETURN. RETURN's are legal anywhere in
a functions or procedure.

Scoping rules in ACTION! are virtually identical to C, except there is no
concept or AUTOMATIC in ACTION!, making recursion more difficult.

Preprocessor (sort of)

DEFINE name="anything"
INCLUDE "filename"

is the only two things. the quotes must always be in the DEFINE statement,
even if <anything> is just a number.

You can have POINTERS to objects and ARRAYS. There is also a struct like
concept called records and are declared as
TYPE name = [BYTE stuff INT stuff ...]

It is C struct and typedef roled into one statement. To use the above the
declaration would be
name myvariable

ARRAYS work just like C. Passing them to a procedure or function just
passes the base address of the array.

RESTRICTION:
You cannot have ARRAYs of records or records with embedded ARRAYS.
There are ways to hack your way around this, however, and the manual
does a fairly good job of documenting it.

Special note:
Anywhere in a program you can start inserting assembly language
for speed. You simply enter
[$00 $00 ...]
where you would normally enter ACTION! statements. VERY handy.
Of course most people use DEFINE and an INCLUDE file to set up
mnemonics for the hex instructions. You are even allowed to embed
program variable names. For example:
DEFINE LDA="$94" ;or whatever it is
DEFINE CMP="$44"

[LDA variable CMP 'T]
would load <variable> into the A register and compare it against
the literal character T

The manual fully documents the operation of the compiler, how it handles
allocating variables during compile time, etc.

The run time library:
Print BYTEs, INTs, CARDs, and strings to standard out, or any other
file descriptor. The I/O subsystem is very similar to UNIX in that
you have a character stream interface based on file descriptors.
Input the above items.
PrintF !!(not all of it of course)

All the normal graphics functions the BASIC(K) has, but as function
calls of course
String copy, compare, substring, etc.
Random numbers
Zero, Set, Move blocks of memory (very fast)
Open, Close, XIO, Point(as in fseek(3)), Tell(as in ftell(3))

There it is. In my opinion, there is no better development environment for
the ATARI 8 bits. (I have never tried KYAN PASCAL). I have been working
with ACTION! for a while and am totally satisfied. Contrary to recent
NETNEWS traffic, it IS!!! better to have the system on ROM, since the
hardware offers your compiler, etc, no protection at all.

191. Re: bad 1050s

Newsgroup: comp.sys.atari.8bit
Date: 1987-02-07 05:40:15 UTC
From: imprint@watmath.UUCP
Message-ID: <4869@watmath.UUCP>
Source record: 117895

Summary:Problem solved

Thanks to all who responded to my plea for help. The problem turned out to be with the mechanism (L.E.D. I think) which tests to see if the floppy is write-protected. It was dirty!

Cleaning it has the drive happily writing disks again.

Thanks again
Doug Thompson

193. Re: uuencoded uuencode for the 8-bits...

Newsgroup: comp.sys.atari.8bit
Date: 1987-02-08 05:25:44 UTC
From: jhs@MITRE-BEDFORD.ARPA.UUCP
Message-ID: <8702080525.AA21769@mitre-bedford.ARPA>
Source record: 117897

Well, it sounds as though your efforts will prove of value to the net, by allowing us to uuencode locally. Since that is done once and decoding is done many times (i.e. by many people), I guess it is not so bad if the encoder is in Deep Blue C and is 5 times slower than the decoder. (I am assuming that encoding and decoding are about equal. Actually encoding may be a little worse because writing DOS files on 1050s is much slower than reading them, and the output file is 33% longer for encoding than for decoding.)

Anyway, thanks for your benchmarking. It is gratifying to learn that I apparently did a reasonable job of structuring the thing for speed.

-John S.

194. Re: modification of end condition test for BASIC uudecode program.

Newsgroup: comp.sys.atari.8bit
Date: 1987-02-08 05:47:09 UTC
From: jhs@MITRE-BEDFORD.ARPA.UUCP
Message-ID: <8702080547.AA21962@mitre-bedford.ARPA>
Source record: 117898

```
Oops! I said OBUF$ and should have said IBUF$, of course...

If you want to modify my uudecode so it terminates on "end" rather than on
the line containing just a space, or in addition to it, then you should test
with
IF IBUF$(1,3)="end" THEN GOTO (wherever)
instead of or in addtion to
IF M=0 THEN GOTO ...
The two tests could of course be combined, e.g.
IF M=0 OR IBUF$(1,3)="end" THEN GOTO ...

I used the simple test for M=0 because I thought it would be the fastest thing
to do.

-John Sangster / jhs@mitre-bedford.arpa

195. Dec Emulators?

Newsgroup: comp.sys.atari.8bit
Date: 1987-02-08 16:39:01 UTC
From: ssegan@dasys1.UUCP
Message-ID: <212@dasys1.UUCP>
Source record: 117899

I use my Atari 8-bit to access UUCP-net, and wondered if anyone knows of any good DEC VT-100 emulators out there for the 48K 800. I'm using a program called VT-10-Squared,which doesn't support ANY file transfers --- not even ASCII! The program I want should have these features:

o ASCII Capture
o 80-column screen with NO extra hardware and NO horizontal scrolling
o Usable on Avatex 1200(Hayes)
o Supports DEC VT100 screen control characters
o Maybe XMODEM????

Does this exist? If anyone wants to see VT-10-SQR,I might upload it in UUENCODE format once someone fixes the decoder so I can decode the encoder.
Thanks,
----Sascha!

Sascha,
You might try Chameleon, available thru ANTIC. I _know_ it does not
offer true 80 columns without scrolling, but it does do many enulations
of which one will probably work for you. It also has good XMODEM and]
Kermit modules ... and a serviceable, if primitive, ASCII text capture.

OK, Dan Fleysher, you're right that I shouldn't have uuencoded this program,
I should have just sent it as a .LST file in ASCII.

It's a simple little random music generator that illustrates some principles
of music theory. The music it makes is not slated for eternal fame, but it is
fun to listen to, for awhile at least.

Enjoy!

Chameleon DOES NOT emulate a VT100, it emulates a VT-52 as well as
others including:ADM-3A, IBM 3101.

The 410 records whatever you feed it just like a regular cassette recorder. But when you try to play it back it passes the output from the tape head (after amplification, of course) through two filters. The output of one filter is a dc voltage if a certain frequency is present, and zero or a lower dc voltage otherwise; and the output of the other filter is a dc voltage if a different frequency is present. I don't recall the actual frequencies, but they were something like 4 khz and 6 hkz, corresponding to the square wave frequencies put out by the serial port when doing a csave or list "c:". The two outputs were combined in a comparator (If I remember correctly) and the final output was a high or low TTL signal. This is what got sent back into the serial port when you loaded the saved program back in. If you grab the signal before it goes into the filters, you may be able to recover the original audio. Also, one of the tracks IS an audio track in that on playback, it gets sent directly to the monitor (TV) speaker. I don't know what (if anything) it does on recording (csave'ing).

Marc Appelbaum claims that Chameleon does not emulate a vt100.
My version (an early one) does not, but I know that later on it
was advertised as a vt100 emulator (complete with 132 columns -- horizontally
scrolled, of course). I never saw this version, but I assumed that it
existed.

There was a mail on info-atari8 dated 2-feb-1987 about a version
of Turbo Basic (interpreter and compiler) for the old ATARI 800.
Could these files please be send to me, or if there is
enough interrest to the whole net?

Could someone please send me the documentation of the Turbo Basic
language or if there is more the whole documentation.

Thank you very much in advance
Ulrich Lang (ZRFA1@DS0RUS51.BITNET
or ZRFA@DS0RUS1I.BITNET)

202. request for pd R: device for joystick port

Newsgroup: comp.sys.atari.8bit
Date: 1987-02-10 09:41:39 UTC
From: ZRFA1@DS0RUS51.BITNET.UUCP
Message-ID: <8702100940.AA08265@ucbvax.Berkeley.EDU>
Source record: 117806

Does anyone have a PD program that installs an R: device
that uses the joystick port instead of additional hardware
like Atari 850? If so, could you please send it to me?
I have seen terminal emulations which are using the joystick
port as RS-232 conection to a modem and thus must have
integrated something like that. I would like to use that
R: device from Kermit in Action!

Thanks in advance
Ulrich Lang (ZRFA1@DS0RUS51.BITNET
or ZRFA@DS0RUS1I.BITNET)

>to do.
>
>-John Sangster / jhs@mitre-bedford.arpa

Please do not do this.

As I posted before, it is the uuencode and not the uudecode which is
broken. The line with the zero byte count (i.e. ' ' or '`' as first
character) is necessary for uudecode.

Since the uu in uuencode stands for 'unix to unix' we really should take
the unix way of doing it as the standard. It seems only marginally useful
to have uuencode/decode for the atari if they are not compatible with
the commonly available programs of the same name.

If I try to uudecode the uuencoded version of uuencode under unix it fails
with the error message 'Short file' (or something similar). This can be
alleviated quite simply by using your favorite editor to insert a line
starting with blank or '`' before the 'end' line. Note that the blank has
to be there, an empty line will not have the desired effect.

At this point the file will decode correctly, although it will produce
the error message 'Missing end line'. This is caused by the fact that
the unix uudecode checks for end followed by new-line, and the file
has end followed by three spaces followed by new-line. This seems a bit
picky, but if the atari uuencode could be modified to produce this line
exactly it would add to the compatibility. Again you can use your favorite
editor to rectify the problem, and then the file will uudecode correctly
and without error message.

I did a bit of experimenting with uudecode and found the following behaviour:
If end is encountered unexpectedly, the 'e' will be decoded to a byte count
of 5, and the characters 'n', 'd', new-line, and some additional ones
(whose origin I could not determine) are used for decoding. If there is more
text, decoding will continue. Only a line with a count of zero will terminate

decoding. I also noticed that the new-line character and assorted junk will be used if the trailing part of an image (including trailing blanks) is missing.

I would like to commend Brad Banko for using trailing characters to avoid the problem of having trailing blanks truncated. Another alternative would be to generate '`' instead of blank. Most new versions of uuencode do this. While it takes a little more processing when generating the file, it results in slightly shorter files.

I would urge Brad to produce a revised version of uuencode which produces the extra line, and maybe fixes the 'end' line too. Meanwhile I urge everyone else to edit their uuencoded versions of uuencode if they want to decode them, and not to hack the uudecode program.

Forgive me if some of the preceding sounds a bit harsh. I did not mean to offend anyone, I just hate to see people spending effort in the wrong direction.

I just looked up the description of the latest version of Chameleon (V. 4.03),
and it does not list it as a vt100 emulator. It does claim either 80 or
132 column emulation (scrolling). It stores and dials up to 16 numbers and
includes Kermit file transfer as well as Xmodem.

Antic does list a vt100 terminal emulator for $10 in the Public Domain
section. I don't know if this is the VT-10sq or not. They don't say.
They do say it works with Hayes compatible modems and interface.

Hope this helps...

206. Re: modification of end condition test for BASIC uudecode program.

Newsgroup: comp.sys.atari.8bit
Date: 1987-02-11 22:16:19 UTC
From: jhs@MITRE-BEDFORD.ARPA.UUCP
Message-ID: <8702112216.AA09244@mitre-bedford.ARPA>
Source record: 117810

Meanwhile, I should modify the BASIC uudecode to treat "`" as the same as a space and perhaps to terminate on encountering "end" just because it seems better than continuing to uudecode! Also, how about uudecode checking the length of the input buffer to make sure there are enough characters there and padding with blanks if not?

-John S.

207. Chameleon

Newsgroup: comp.sys.atari.8bit
Date: 1987-02-12 00:36:00 UTC
From: IHLS400@INDYCMS.BITNET.UUCP
Message-ID: <8702120645.AA20640@ucbvax.Berkeley.EDU>
Source record: 117811

I have used Chameleon for about 4 years. Up until recently I was using version 2.0. I got V4.03 from Antic about a month ago and have been using it happily ever since.

Chameleon does NOT emulate a VT-100. It does, however, emulate a Glass TTY, ADM3a, VT-52, VT-52x (extended) and IBM 3101.

It supports a number of file transfers including simple capture, XMODEM and Kermit (which is why I wanted to get V4.03 in the first place).

I have only two complaints about Chameleon. The documentation is found on the back of the disk. It can be printed or displayed via the program that boots up that side of the disk, but I miss the nice, readable, semi-indestructible manual that came with V2.0. Also, Chameleon will not recognize that it can indeed dial my modem (Volksmodem 12 through the 850), and I am forced to <escape> to the main menu and START the communications on my own. I'll get over it. (Yes, you may infer from this that you can indeed store the numbers of your favorite dozen or so computers.) Make that three complaints...V4.03 does not save the filename to which you may routinely download (or in my case "snapshot" the screen...which I do to the printer frequently...) in its parameters.

Chameleon is available through the Antic Catalog for $19.95 and it only took about 2 weeks for it to be delivered, and I sent a personal check as payment!

Please feel free to contact me directly if you have any questions about Chameleon. I will be happy to try and answer them.

Message-ID: <8702120249.AA14385@gateway.mitre.org>
Source record: 117812

Help! I have a Ventel 1200-31 Hayes compatible model hooked
to my 800 (not XL) via an 850 interface. I can dial from the
terminal mode screen directly, by giving AT commands from the
keyboard. My problem is that the Chameleon dialing menu doesn't
seem to work properly. I can see something being sent to the modem
(and echoed back depnding on switch settings). But no further
interaction (no off-hook noises or LED) to denote progress.

Does anyone have this setup, or could you tell me the proper settings
of the Hayes modem (Either physical switches for echo, result codes, verbose
mode, etc) or for the Snn software switches to make this work?
Thanks in advance.

Walt

212. PD Vt100 in Antic

Newsgroup: comp.sys.atari.8bit
Date: 1987-02-12 19:29:00 UTC
From: IHLS400@INDYCMS.BITNET.UUCP
Message-ID: <8702122239.AA06345@ucbvax.Berkeley.EDU>
Source record: 117816

The PD VT100 emulator available for $10.00 through Antic is indeed VT10SQ. It's not bad but fairly inflexible and a bit tough on the eyes at times. It's not quite a full emulation, but it does in a pinch when I can't tolerate Chameleon's horizontal scrolling. Again, the documentation is on the back side of the disk as it is with Chameleon. I also have the TEK4010 emulator, but have not used it extensively yet... just a bit. It does seem to work as advertised but documentation is basically non-existent...

Regarding the problem with Chameleon not believing that it can dial those numbers, I called Antic's service people... (I had tried about every switch setting I could think of)... They said that it probably was just because the modem was 100% Hayes and I could exchange Chameleon for something else if I wanted... (No way!) Chameleon won't hang up the phone for me either. I can cope with both problems. When it tells you that it can't dial that number, <escape> into the main menu and START communications. Chances are it really is dialing (and you can see it do so if you <esc>START fast enought). It's just lied to itself and won't start communications of its own accord. Then when I'm done, I simply do the +++ and ATH by myself instead of having Chameleon do it. It's a small price to pay for Chameleon's flexibility...

Once again, if you have any questions that I might be able to answer, feel free to contact me.

Source record: 117819

Dan,

I have hooked a terminal up in place of the modem, just to see what Chameleon has sent towards the Hayes. It only sends a carriage return and a capital A. Unless this is an old Hayes command set, I don't see how this would ever work (the Hayes expects "AT" before all commands).

I may take Marshall Abrams suggestion and just use the native Ventel mode, since this offers stored numbers, too, plus autodialing. That might even be fewer keystrokes(!), but you lose the name and baud rate features of Chameleon's phone directory.

216. Review of AW Plus

Newsgroup: comp.sys.atari.8bit
Date: 1987-02-14 01:08:48 UTC
From: appelbau@topaz.UUCP
Message-ID: <9232@topaz.RUTGERS.EDU>
Source record: 117820

This review appeared in the Feb. 1987 issue of the Micro's of Monmouth Atari Computer Group Newsletter and may be reprinted provided MOM and the author get credit.

AtariWriter Plus
Atari Corp.
P.O. Box 61657
Sunnyvale, Ca. 94088
List Price: $49.95
Min. 48k RAM

Reviewed
by
Marc L. Appelbaum

AtariWriter Plus (AW+) is an upgrade to the original AtariWriter (AW) word processor. AW+ can be used with any 8-bit Atari with at least 48k. If you have an Atari 130xe you can take advantage of the extra memory by using three banks of 15k (15,872 bytes.).

To load AW+ insert the disk, making sure that the right side is up, (side A-48k, version, side-b 128k version.) After it loads you will see the familiar AW menu with a few new options. The first new option is the ability to get a directory of drive 2. The second addition is Verify Spelling, the third is Global format, and finally Mail merge.

Lets look at the menu:
C-create file, create's a file
E-Edit a file, edit an existing file
V-verify spelling, discussed later
P-print file, discussed later
G-global format, discussed later
1-index drive 1, gives a directory of drive 1
2-index drive 2, gives a directory of drive 2
L-load file, loads a file into memory
S-save file, saves a file to disk
D-deletes a disk file
F-format disk, formats a disk

The verify spelling option loads the Proofreader into memory. Then displays the Proofreader menu. The menu has a number of options on it. I will only look at a few.

The correct errors option will proofread the file and stop when it finds an error at which point you'll be able to change the word, perform a dictionary search, or continue. Highlight errors, will proofread the file and highlight the errors in inverse video. Print errors will print out a list of errors. Dictionary search will search the Proofreaders dictionary for a specific word. Add personal dictionary is what I consider to be the most powerful function of Proofreader. It allows you to add a dictionary file that you've created to the programs dictionary. When the program proofread's your file the words in you dictionary will be included in the search. To create your dictionary file just

create a file, the same way you normally would and type in the words you want toy files as you. I have two, one for work, and one for personal use. The one for work includes words such as:Rutgers, CCIS, Microlab, consultant, RAM, ROM, CPU, DEC, UNIX, etc.. The one for my personal use includes the names of my entire family, street names, town names, etc. Figure 1 is part of my dictionary file for work.

The file personal dictionary option will save any new words to a file. By new words AW+ means words that are not in its dictionary.

Return to AW+ just returns you to the main program.

The print file option from the main menu will bring up another menu which will ask you want printer you have. It lists all the ATARI printers, if you type "H" for other printers it brings up another menu, this one list drivers for various other printers. If yours in not you can type "O" for other, and AW+ will ask you for the of the printer driver file. Once you select a printer type it remains in memory until you turn the computer off.

You can also print to others devices instead of the printer. You can print to disk(i.e. print to d:file.prt.), cassette, or to the RS232 port.

Global format allows you to change the format commands. It is equivalent to the first line of a AW file. You may or course insert formatting commands within your file.

Building your own Printer driver

To create your own printer driver boot AW+ with BASIC inserted and HOLD down the SELECT key until the Custom Printer Driver screen comes up. You'll then be prompted to enter the control codes for various functions. These codes can be found in the back of most printer manuals. When you're done creating you driver you'll be asked for a file name. Do NOT enter a file name with an extension. AW+ adds its own extension PDF (Printer Driver File.)

The editor

The editor is very similar to AW, with a few new options. In AW+ you can choose between insert and type-over mode by hitting <control>-insert. Insert mode is the default mode. As you type the text moves over to the right. In type-over mode you type-over existing text. AW+ also has the option to change the number of columns displayed on the screen. The default is 38. I use 80 columns if I know that I'm going to upload the file to a mainframe. This way I

center things on the screen without having to worry about deleting control characters later. However the screen can't display all 80 at once, so it scrolls to the right. Supposedly the when the new XEP-80 comes out you will be able to see al 80 columns with a new version of AW+. An added feature which I like a lot is the ability to save a block of text to disk. Another new feature is the REVERSE search. This does exactly what is says. It performs a search starting from the cursor to the beginning of the file. AW+ allows to alphabetize a block of text. This comes in handy if you want to have a print out of your dictionary file. To alphabetize a block you simply press OPTION-B to mark the beginning of the block, highlight the block with the cursor, then press OPTION-A and AW+ will do the rest. AW+ also has the ability to save a file in ASCII format. You do this by typing <control>-s at the main menu. You would use the feature if you're going to upload the file to another computer, or you're going to use the file with an other editor.

The Mail Merge

The mail merge option loads another program called Mail Merge. It's actually a mini-database. I have no need to use this function at all, because I use Synfile+ as my database. Both Mail Merge and Synfile+ share data with AW+ in the same way, as they did with AW.

Overall I've no major problems with AW+. If you've worked with AtariWriter before, then AW+ will be extremely easy to use.

217. UUDECODE.LST Version 1.1

Newsgroup: comp.sys.atari.8bit
Date: 1987-02-14 03:08:13 UTC
From: jhs@MITRE-BEDFORD.ARPA.UUCP
Message-ID: <8702140308.AA02651@mitre-bedford.ARPA>
Source record: 117821

Here is an updated version of my UUDECODE program for the Atari 8-bitters. This version has worked correctly on the few cases I have tried. Bug reports will be cheerfully accepted, however.

Version 1.1 differs from 1.0 chiefly in that it will accept a <RETURN> instead of a filename for the output file when decoding. In this case it will assume the device id D1: and will extract the filename, if possible from the "begin" header line of the file. If it can't figure out a valid filename, it will again prompt you for a filename, but since this happens after it has displayed the "begin" line on the screen, you will at least have a clue as to what might be a reasonable filename. (NOTE: I sidestepped the thorny problem of parsing filenames by letting the O/S do it: I used a TRAP statement to tell me that the O/S didn't like the filename.)

This version will also skip header and trailer text. This means that you can uudecode from a message that contains explanatory comments before and/or after the actual uuencoded data, and uudecode will still produce a correct output file. The only requirements are that the uuencoded data must begin with a "begin" line and end with a line containing a space in the first character position, followed by a line beginning with "end".

I still have not included the masking that Hans Breitenlohner suggested in the assembly language routine. I hope to get to that soon. Meanwhile, if $60 appears in a uuencoded file that you wish to decode, it will be necessary to map it into $20. This can be done for example on unix systems with a "tr" command. Also, if the network removes trailing blanks, that may cause problems. Sorry for the inconvenience.

I suggest the name UUDECODF.LST rather than UUDECODE.LST ("F" for filename handling) at least until you decide that you don't need the older version.

Here goes...

-John S.

Chameleon's opening screen offers a selection of modem connections which I have listed here for those of you who want to know before plunking down your $19.95.

0) None (demo mode)
1) 850 interface
2) 850 with Hayes Smartmodem or compatible modem (or in my case semi-compatible)
3) 835
4) 1030
5) 1450xld internal modem

Also, you might be interested to know that V4.03 has a Utilities option which allows you to perform some DOS functions.

two magnifications of what Holly says about chameleon:
1) i have succesfully used chameleon with an xm301 modem by choosing the 835 modem as the default... for some reason, i don't know why, the 1030 didn't seem to work... now i am using it with an avatex hc with the 850 interface option, i have had some luck off and on getting the autodial menu to work that way, but i don't think i've been able to get it to work with the Hayes compatible option... the hc is very compatible... i think i have figured out that in order to get it to autodial you have to go into terminal mode and hit shift-caps to put chameleon in upper case mode... that may be the only problem, and might also make it work with the hayes option...

(the avatex 1200 hc is much better than the avatex 1200... for the extra $50 that the hc costs, you get most of the AT command set, a speaker, no need to switch baud rates manually, and the S register functions...)
2) the chameleon dos utilities menu has most of what you need from the dos 2.x menu world... directory with wildcarding, copying (as we all know by now, using the device names E: and P:, this allows you to view a file or print it by copying it either to

E: or P: respectively)... i have been using it under spartados,
and it works just fine... that John Palevich is/was a great
programmer...

220. ?spaces in true uuencoded files...

Newsgroup: comp.sys.atari.8bit
Date: 1987-02-14 19:19:25 UTC
From: btb@ncoast.UUCP
Message-ID: <2068@ncoast.UUCP>
Source record: 117824

i have tried out the uuencode on our unix system here, and it does indeed put spaces into the uuencoded lines... this makes sense, anything else wouldn't be compatible across machines... somebody had mentioned that a turbo basic uuencode program on the ibm pc put something else in place of spaces (i believe it is a grave accent)...

that's (i'm sorry, i meant turbo pascal), turbo pascal & ibm for ya... leaders in screwing up sensible standards for years...

222. Re: Some comments on the "alleatoric music generator".

Newsgroup: comp.sys.atari.8bit
Date: 1987-02-17 15:37:30 UTC
From: jhs@mitre-bedford.ARPA.UUCP
Message-ID: <8702171537.AA03920@mitre-bedford.ARPA>
Source record: 117826

Brad:

No, I don't think I saw ARC for the 8-bitters. Would appreciate a copy. I don't know how I missed it, but I did.

Glad you liked the random music generator. It shouldn't be hard to play around and find even better algorithms for note/chord selection. The present version which uses small steps up and down is far more musical-sounding than the first attempt, which picked the notes at random. The construction of chords was very ad hoc, the key (so to speak) point being that all the available notes are half-tones in the tempered diatonic scale (translation, all frequency ratios are powers of the twelfth root of two). I experimented and found that the rules for picking steps to make a chord that I have in the program sounded pleasant, so that is where it rests. Much improvement is doubtless possible.

I think the best addition now would be some logic that remembers runs of notes and throws in repetitions of one or more of them. Maybe four memories for sequences, and let it pick the length and the sequences at random, but multiples of 4 notes in a sequence (in 4/4 signature). Then assign some different probabilities for starting a repeat. You could even impose patterns like having one of the sequences always show up as a "chorus" the end of each "verse" or whatever the correct terms are. Might also throw in a rule or two to make the final chorus end up on a "tonic" chord, meaning you would have to pick a key -- or the program would, at any rate.

-John S.

223. US DOUBLER SLOWER SOMETIMES??

Newsgroup: comp.sys.atari.8bit

Spartados and Action users:

Question for y'all -- before putting bread on the line to buy Spartados/US doubler (mainly for use with Action programming) I want to clear something up:

I have heard that the hi-speed write and read applies only to binary files; and that Sparta with doubler actually works more slowly than other DOS's with other file types.

Specifically, does it really work more slowly reading/writing Action source code files, than say Smartdos etc?

224. Need much info on Supra 1200at

Newsgroup: comp.sys.atari.8bit
Date: 1987-02-18 22:54:42 UTC
From: mahlen@brahms.Berkeley.EDU.UUCP
Message-ID: <992@cartan.Berkeley.EDU>
Source record: 117828

I just bought a Supra 1200at and darned if the documentation is meagre!
What little there is claims that this is, in fact, an Avatex 1200. It only
came with a piece of software called Smart Terminal, which is neither. I
would really like to be able to edit files remotely, and am sort of willing
to write the emulator (though i'd rather not), but i have no clue as to how
to send the modem commands. The modem came with a single serial -> rs232
converter (it's a serial cable, then a little box, then the rs232 cable).
I've tried making the RS232.COM file from Indus Dos 2.35i the AUTORUN.SYS
file on a disk, but the R: handler either isn't loading or isn't installing
itself. Does anyone have a real terminal program for the Supra 1200 (great!)
or at least know how to let me talk to my modem without using Smart Terminal?
I used to think i was a pretty competant (sp) programmer, but this
tele-communications stuff leaves me baffled. Any ideas?

mahlen

p.s., the modem commands run like ATDTphoneno and >A. Does this protocall
look familiar or have name?

"If you smile too much, your neck will melt."
"If you nech too much, your smile will melt."
Barrington graffiti

p.p.s, Does anyone know the net address of Atari? I think an old friend of mine
works there. Mark Cerny, where are you, this is your past calling....

>or at least know how to let me talk to my modem without using Smart Terminal?
I have seen two flavors of modem handlers on Ataris: The R: handler, which
is usually downloaded from the 850 interface or equivalent, and the T: handler
which is usually loaded from disk. The AUTORUN.SYS on DOS-XL disks just
loads the R: handler from the 850, and won't help if your interface is not
prepared to download. You did not say if your interface has any recognizable
name. I would check the disk which came with it for any files which look
like a handler (which you would have to append to any modem program you
want to use with it), and maybe even some documentation.

226. Ghost Busters Info wanted

I have a Ghost Busters game for my 8-bit Atari 130XE. I don't have the instructions, Would anyone happen to have any idea what the game is all about.

Hints: It starts off by you selecting a car and some other equipment to capture the ghosts. Then a map of the city comes on and ghost start to appear and then you lose.

I would appreciate any help in this matter.

>
> I have heard that the hi-speed write and read applies only to binary files;
> and that Sparta with doubler actually works more slowly than other DOS's with
> other file types.
>

The hispeed read write works on ALL files.
----- BUT -----

In the Action world there are several buts.
When Action reads in a source file, it does not do a binary read. It
reads the file a little slower sector by sector. Remember that the main
part of the hispeed process is in a different sector layout on the disk.
When Action reads a source file it takes a little processing time, which
may allow the diskette to spin past the next sector before the read request
gets to the drive. This will indeed make it a slower read for Action
source code.
A new sector layout for Action disks would help, but not a good idea!
Another problem that comes up is the fact that Action doubles the key
repeat rate AND Sparta DOS doubles the key repeat rate. Unless you
change the key repeat rate with an AUTORUN or something it is almost
unuseable.

I LOVE Action and I like hispeed!!! My solution.

I use MYDOS for all my disks. It is totaly compatable with all my old
DOS 2 stuff. There is a file on Compuserve that is an overlay for the
XE/XL operating system that replaces the cassette handler with the
hispeed handler. Now any DOS uses hispeed. This takes care of the
computer end of the system.
On the Drive end, I use the board from Duplicating Technologies. They
have two versions (two prices) either one gives me what I want. HISPEED.
This is a different method (the Happy upgrade does this too) It adds
extra RAM in the drive so it reads a whole track at a time instead of
a single sector at a time. This allows me to use normal sector layouts
and get hispeed reading. (not writing) When Action reads a source file
the first track gets buffered in the drive and the sectors are ready
as soon as the next read request gets to the drive. This gives you
max speed with an slight delay for each new track. Of course this speed
increase works best on orderly file layouts on the disk. If the file
is scattered all over the disk, this slows down the system.

At work I use the modified OS and a 1050 with the US Doubler and custom sector layout running MYDOS. This is a very nice combination.
But, yea I know, one more BUT. This combination does not allow you to generate the custom sector layout. I use the Archiver in my 810 to generate the fast sector layout that you would normally get from Sparta DOS.

I hope that somewhere in my rambling I have given you some useful info.

What terminal type do Chameleon users set themselves to when calling
a Unix system? I haven't been able to find a combination that works
with the VI screen editor (cursor motion, line inserts, etc).
Chameleon doesn't react much at all to the VT52 termcap, with ADM3A
I have to set even parity within Chameleon, but there still is no
cursor movement. I don't know what the IBM flavor is that is supported
in Chameleon. (By the way, the issue arises because I have always
used ED as my editor when dialing in, but decided to use VI now).
Any help is appreciated! (My version of Chameleon is 4.0).

The Supra 1200at sounds like the same idea that Nite Lite Systems sells as an interface to the Avatex 1200: a re-invention of the R:Verter concept. Maybe if you can find a driver for the R:Verter, it will work with the Supra as well. Certainly an ordinary RS-232 driver won't work.

Basically, the R:Verter is a TTL to RS232 level converter. (Cheap, huh!?) It sits on the SIO line, which is basically a TTL serial Async interface without all the usual handshake signals. The R:Verter lets you tie it to a device that expects RS-232 levels. All you need is a piece of software (driver) to patch it in to the normal R: interface that the CIO knows about. (Somebody who really knows what they are talking about might care to comment at this point, or better yet, to supply a copy of the R:Verter driver.)

If you are REALLY stuck, you might try to prevail on the good nature of Paul Swanson, owner of Nite Lite Systems, for help. I believe he DOES supply a driver with his modified Avatex. Paul can be reached via BBS at (617) 663-4221. He does have a voice line but doesn't like to be pestered there as he is quite busy trying to make a living as an Atari sales and service dealer and creator of fine hardware/software products for Ataris.
(If you have no way of reaching him via the BBS -- e.g. 'cause you can't get your new modem to work -- let me know and I will send you his voice line number.)

The USDoubler achieves fast read/writes by a combination of track buffering
and custom disk formatting. The speed is not dependent on the type of files
being read; all that matters is that standard CIO calls be used to do the
i/o. SpartaDos is the _only_ DOS which can achieve optimum disk formatting
by using a special interleave. If you stick to it (and there's no reason
not to these days) you will get rapid i/o regardless of file type.

I use the VT52XL emulation all the time with an Atari 130XE/Hayes compatible modem and an 850 interface. Vi works fine, everything that you mention works as if I were on any other terminal.

I use the following setup:

Terminal: VT52-XL
Back space: CTRL-H
Parity: off
Duplex: full
Flow control: ^S/^Q

With this, I get full cursor motion, line insertion/deletion, character insertion/deletion. I have seen similar problems to yours before, it usually is because either parity is on even or odd or flow control is not properly set up.

I have also used an 800XL with the above setup and have had the same results. Have also used a 1030 Atari modem at 300 baud, is slow as all get out, but also works. My Hayes compatible is a U.S. Robiotics Courier which I run at 1200 baud, that I borrow from work. When you are using Chameleon and an Atari computer, you can get { and } by using CNTRL-; and CNTRL-< (^; and ^<). H is your left arrow, J is down arrow, K is up arrow, L is right arrow. Use i, r, R, a, etc. commands for insertion, replacement, Replacement, appending, etc. just as if you were at any normal terminal.

Why didn't you keep the directions when you purchased the program?
The directions are quite explicit as to the purpose of the game. Of
course, this is presuming that you *bought* the game...

Source record: 117839

This is a progress report on the efforts underway to make the info-atari archives available to all subscribers by transfering them to LISTSERV on Bitnet. In order to make this service work, we need additional volunteers.

The mail digests are being made ready; will will be sending out a message concerning them very soon. But now we need to do some work to get ready for program archives. The first task is to set standards for programs. I have some ideas about minimum standards for documentation and testi to make sure that programs work as advertised.

I think it would be a good idea to review all the program files on Score.Stanford before transferring them to Bitnet. I am looking for volunteers to do this reviewing. We would want to separate the 8-bit and 16-bit files at this time.

For steady state, we would need moderators to receive contributions, review them to make sure that they meet the above standards, and to place them into LISTSERV. As I understand the process, it would be necessary to this (these) moderator(s) to be on Bitnet.

Will you please respond to me at Mitre if you would like to volunteer.

Sincerely,

- Marshall D. Abrams, info-atari moderator

All

The demise of the 8-bit by atari still seem eminate. When 8-bit users contact atari,thru ATARI BASE,genie,NET or other info nets, Atari does not usually reply. Atari only claims to supporting the 8-bits is the xm301 modem. Though atari has promised the xep80 and the 3.5" drive. One of the reasons atari can't seem to support the 8-bits is the need to enter the IBM PC/clone market. The atari PC and the 68020 take up all of atari's research time and money. I'm sure the 8-bits have been moved to the back burner.

ATARI(Neil and other who might still keep up with the 8-bits)

If Tramiel wants to rake in the allmighty cash from the PC compatible market,or any other market he sees, thats fine. But don't let Atari 8-bits die by lack of action on atari part. If you do the ST user will wonder what will happen to them in the near future(2-3)years, when the next MACHINE is ready. If atari is no longer willing to support the 8-bit. Sell its copyright to ICD or some other company that will do something with it. Disclose the architecture of the 8-bit custom chip. I'm sure atari could do this since the old atari held the patents or copyrights to everything its employees did.

THE AMIGA 2000 is starting to look like it will be my next upgrade!

I set my term type to ATARI using the following .termcap

```
'atari|atari|Chameleon VT-52xl:so=\EF:se=\EG:al=\EN:dl=\EO:im:em:ic=\EL:dm:ed:dc=\EM:bs:cd
=\EJ:ce=\EK:cl=\EH\EJ:cm=\EY%+ %+
:co#80:li#24:nd=\EC:pt:sr=\EI:up=\EA:ku=\EA:kd=\EB:kr=\EC:kl=\ED:';
```

Also place the following lines in your .login or .profile:

```
echo -n "Terminal type: "
set term = $<
if ($term == "atari") setenv TERMCAP ~/.termcap
endif
setenv TERM $term
```

Set Chameleon to:
term type:VT-52XL
Backspace:rubout
Parity:None
Flow:^S/^Q

Source record: 117846

Have considered getting an Avatex modem, but since I can borrow the US Robiotics indefinitely have not felt the need. Will probably get around doing it eventually. Right now, my $ are going to my first hobby -- model railroading. Which brings me to a question: do you happen to know any model railroaders who are also good Atari programmers (in any langauage, but preferrably BASIC XE)? Am trying to get a program converted from TRS-80 BASIC for several years and have not been able to get it to work. Would like to have someone of like interests willing to help write a program to do the same thing from scratch. Essentially it is a program to setup waybills and generate traffic for prototype operation of a model railroad layout. Requires a large data base for all industries, cars, commodities, etc. and thus would be ideal to utilize the 130XE extra memory (or better yet a 256K upgrade). The NMRA (National Model Railroad Association) does have a computer SIG, however, most that I have been able to discern is that they are IBM/TRS80/Commodore programmers -- Atari and model railroading seem to have not come together. Why, I do not know, I think we have as much capabilities as anything short of the IBM's and since I use an IBM XT at work, I often wonder about that. I still maintain that there are a lot of things that my Atari 8bitters can do or are set up to do, that I have to get additional boards, set dip switches, etc. on the damn IBM to get the same capability. Still, being able to boothe 130XE, suspect that you can not set up the hard disk to AUTORUN.SYS, however.

--Bill--

(Would also be nice if the 8 bitters could "AUTOEXEC.BAT" -- .BAT files are good IBM invention. I suspect that if I was more getting skilled, I could probably do the same thing with the AUTORUN.SYS file.)

244. Re: A friendlier, fixed UUDECODE 0.6F

Newsgroup: comp.sys.atari.8bit
Date: 1987-02-25 02:23:11 UTC
From: bammi@cwruecmp.UUCP
Message-ID: <1892@cwruecmp.UUCP>
Source record: 117848

the protection mode in a uuencoded file is the read write protection mode for Unix uudecode to use for the uudecoded file... (i.e. it sets whether you, your group, and others (everybody else) on a Unix system can read/write/xecute the file). It is included in uuencode.com mainly for compatibility. (The default that I use, 700, means rwx permission for the file owner, no permission for anybody else... I didn't mean to be anti-social, but this seemed to be the safest default to use. If you uudecode such a file on a unix system and want to change its protection mode, see 'man chmod' which tells you how to do it.)

the 'outbytes/line' parameter is in there because it was not clear to me when I wrote uuencode how flexible the length of a uuencoded line is... from what i could tell (and john sanger sent to me) it was typically 45 bytes/line encoded to produce 60 characters plus the leading 'M' (typically) and the trailing 'a' (to protect trailing spaces)... the way i wrote uuencode it seemed that the sensible thing to do was to limit the 'outbytes/line' to be a multiple of 3, so that groups of 3 bytes encoded into 4 characters were always on a single line (i.e., didn't get split across line boundaries). i don't know if standard uuencode is limited this way, but i did find a good use for leaving this parameter in... (particularly while debugging it)... by using an 'outbytes/line' smaller than 45 (but still a multiple of 3) you can create uuencoded files that have less than 40 characters on a line, and hence you can display them on your 40 column screen without the lines annoyingly breaking over at the end of the screen (e.g., outbytes = 27 gives 36 + 2 = 38 characters/uuencoded line...) this makes it more aesthetic if you have some need to edit the uuencode (.uue) file on your 8-bit... which brings me to:

the most recent version of uuencode.com that i posted was 2/6/87. it had all of the fixes that i have know about (particularly related to handling the last line, and putting a blank line before the 'end' line). the only fix i have been made aware of since then is that there are three trailing spaces on the 'end ' line that unix uudecode complains about... i don't know if this leads to a misdecoded file on unix systems, or not, but i am pretty sure that john sanger's uudecode.bas (and my uudecode.com) handle this ok... (come on, unix uudecode! i put the blanks in either by accident, or to distinctly mark 'end'...) i have fixed this, but haven't posted the fixed version, because 1) maybe it really isn't necessary (you can use an editor to remove those trailing blanks before uudecoding, if you need to), and 2) i am pretty sure that john and my uudecode programs handle this case ok.

if this is more than a minor hassle to you, send me mail (DON'T REPLY TO THIS MESSAGE!!! send me mail at the address below, since

I am using a friend's account right now.), and if there is enough
interest, I will post the most recent version of uuencode.com.

I will try to remember to post vt10^2 and the docs soon since there is
interest.
bye :-)

I will post the 1030 version as soon as I can.
The 1030 version is an addition to the 850 version which I posted.
It will work also with the 850, it's just a little bigger.

246. uudecode.bas update - Version 1.2a

Newsgroup: comp.sys.atari.8bit
Date: 1987-02-25 19:44:35 UTC
From: jhs@MITRE-BEDFORD.ARPA.UUCP
Message-ID: <8702251944.AA12989@mitre-bedford.ARPA>
Source record: 117850

Here is a revised uudecode.bas with some new features. Actually the file appended here is in .lst format and is NOT uuencoded.

Version 1.2a has the following (I hope) improvements.

(1) It checks to see if the input lines are shorter than 61 bytes, and, if so, pads them out to full length. This should fix the trailing blank truncation problem. (This is done in BASIC in Line 40.)

(2) The ML subroutine masks off all but the low 6 bits after subtracting 32 from the input bytes. This should fix problems with uuencoders that encode 0 into $60 instead of $20.

(3) Version 1.2a has fixed a bug by inserting a TRAP 2095 in line 2044. Handling of "ABEND" conditions (God, I love that old IBM jargon!) (abnormal End-Of-File) is now correct. (Guten Abend!)

(4) This version now loads the subroutine just once and asks you if you want to uudecode any more files after doing one. All pretense to including uuencode has been removed (I once planned to combine the functions in one program but now believe that is not desirable).

I am sorry to say I haven't seen the derived version of uudecode with an improved user interface yet, but perhaps the author will update that to incorporate the improvements from version 1.2a.

-John Sangster / jhs@mitre-bedford.arpa

247. Kitchener-Waterloo Atari User Groups

Newsgroup: comp.sys.atari.8bit
Date: 1987-02-26 14:03:29 UTC
From: daroloson@watmath.UUCP
Message-ID: <5449@watmath.UUCP>
Source record: 117851
Cross-posted to: kw.micro,ont.micro,comp.sys.atari.8bit,comp.sys.atari.st

There are currently 2 Atari user groups in the Kitchener-Waterloo area.
Both consist of 8-bit and 16-bit enthusiasts
(20 to 40 people each meeting), meet monthly, have
special interest groups (SIGs), associated bulletin boards
and public domain libraries.
They are called GTIA (Get Together for Information on Atari) and Vector II.

I am currently vice-president of GTIA
and room-coordinator for Vector II,
so I should be able to handle most questions or
get replies from the rest of executive.
I am also currently giving Basic tutorials, hosting
the 8-bit Machine Language SIG, will be giving a
demo of Action! (language & compiler for 8-bits)
at the next GTIA meeting, and hopefully
starting Action! tutorials and/or SIG afterwards.

Both groups welcome new members and visitors with
8-bits, 16-bits, or those just curious.

Dani Roloson

248. turbo basic for 400/800

Newsgroup: comp.sys.atari.8bit
Date: 1987-02-26 19:02:19 UTC
From: dales@zaphod.UUCP
Message-ID: <1208@zaphod.UUCP>
Source record: 117852

One more 800 (actually upgraded 400) user here. I would
very, very, much appreciate a copy of the Turbo Basic System and
documentation that runs on the 48K RAM 400/800 systems. I have
seen people talking about it and requesting it. Please can
someone mail a copy to me.

Also, if anyone wants to upgrade a 16K board to 48K I have
a quite explicit article I wrote that I can mail if you provide
a SASE. Be prepared to spend some quite a few hours removing
chips, cutting and retouting traces and piggybacking some chips
back down. It can be done though, requires 3 extra LS TTL chips
plus 8 4164's.

Thanks in advance,

>-John Sangster / jhs@mitre-bedford.arpa

If I have followed this correctly, this Avatex 1200 modem can be used
to access vax unix from an Atari 130x. If not which modem should I get.
Also, will I need a terminal emulator? I am new to PC's and don't
have a clue. Please help!!

Thanks,

Dan Boskovich

250. Model railroading; autorun files

Newsgroup: comp.sys.atari.8bit
Date: 1987-02-28 02:40:29 UTC
From: abrams@MITRE.ARPA.UUCP
Message-ID: <8702280237.AA17271@chance.mitre.org>
Source record: 117854

Here's one more model railroader who also is into Atari. But I'm afraid that I'm not very interested in programming the train order system you mention. I did program a big system on the Atari, namely The Print Tool (RUNOFF), and haven't been too interested in any programming since. However if you have a problem, I'd be happy to discuss it. Also, my equipment is not the newest -- I'm running a 400 with 48K and a detached keyboard.

Concerning AUTORUN, let me make two observations. I have a program which patched DOS 2.0 to change the name of the AUTORUN file. I have no idea if it will work with DOS 2.5. DOS-XL does have an ability to run a COM file upon bootup. I don't remember the details; I used DOS-XL for a while, but reverted to Atari DOS.

Sincerely,

Dan Boskovich asks:

"If I have followed this correctly, this Avatex 1200 modem can be used
to access vax unix from an Atari 130x. If not which modem should I get.
Also, will I need a terminal emulator? I am new to PC's and don't
have a clue. Please help!!"

Yes, the Avatex has worked out very well talking to a VAX at 1200 baud from an Atari 800XL. However, any 1200 baud modem would theoretically do the job. The Avatex has the virtue of being about the cheapest 1200 baud unit around, at $75 to $80, especially considering that it has autodial, autoanswer, and autobaud features. Since you are new to all this, let me explain briefly. Autodial capability lets you send commands to the modem which make it dial the phone automatically. The Avatex (or any Hayes compatible) will dial either in Touch Tone or Pulse mode depending on which command you send it. For example you send "ATDT5551212" to it and it dials 555-1212 in Tone mode. The "AT" stands for "Attention" -- gets the modem's attention -- and "DT" means Dial, Tone Mode. The digits are of course the phone number.

Autoanswer means the modem will answer the phone and put out a carrier so you can run a Bulletin Board System from your computer if you wish.

Autobaud means it will automatically switch to the correct baud rate, 300 or 1200, depending on what it sees on the incoming line after it has answered the phone.

There is a more expensive Avatex, the 1200HC which is fully Hayes Compatible. This includes a built-in speaker which lets you follow call progress. With the cheaper unit you have to plug in a phone in the jack on the back if you want to listen. The 1200HC sells for around $110 to $150 depending on your source, and will probably work with a wider assortment of Bulletin Board software than the plain 1200. The $75 Avatex 1200 has done everything I need so far, however.

You will need the modem, an interface, and a terminal emulator to get started. If you want to make the Atari look like a VT100, the VT100 emulator which was posted in the last Info-Atari8 Digest will do the trick. However, if it is as I think it is, it will not help you with downloading files, which you will want to do to benefit from the many fine Public Domain programs posted on this net. Other terminal emulators are available which will help with that. The one I use is CDY's OmniCom, which provides "kermit" and "xmodem", the two most popular protocols for transferring files reliably. OmniCom requires CDY's OMNIVIEW chip, but with that you also get 80-column display capability for word processing and not just for terminal operations.

As for interfaces, the P:R:Connection and the Atari 850 are two of the most versatile choices. Each will let you hook up an industry-standard printer (so-called Centronics style parallel interface) as well as two (P:R:C) or four (850) serial devices, one of which will be the modem. The P:R:Connection has been selling for around $55 and the 850 for around $109 by mail order, though I just noticed the 850 listed for $99 from Electronic One in Columbus, OH. (Phone (614) 864-9994; P.O. Box 13428, Columbus OH 43213.) Though you can get modems with direct Atari interfaces and whatnot, I strongly recommend getting one of the two interfaces mentioned above so you can use standard modems and printers which you can keep and use with another computer that you may upgrade to later on.

From: vax135!art@ucbvax.Berkeley.EDU (Arthur Schmidt)
Subject: technical data request

"If anyone has an answer to Don Brown's request, please forward
the info to me as well. I am interested in where I can get my hands
on technical hardware and software info on all of the atari 800 family..."

Atari Customer Service can sell you both hardware and software manuals on the 400/800 and XL/XE series, as well as peripherals. Included are the schematic diagrams, the Operating System source code, etc. There is also a fine book called de re Atari, which is a must for anyone wanting complete information. Then there is Inside Atari DOS, and the Atari BASIC Source Book, both of which contain source code listings. Finally, you MUST have Mapping The Atari. SAMS ComputerFact manuals are also available with schematics and repair information. THAT should keep you busy for awhile!!!

255. Chameleon and termcap entry

Newsgroup: comp.sys.atari.8bit
Date: 1987-03-02 17:44:03 UTC
From: crd9852@ritcv.UUCP
Message-ID: <137@ritcv.UUCP>
Source record: 117759

When I dial in from home with my 800XL and chameleon I have noticed something peculiar with the backspace key. When I have the shell prompt (I guess that's what you call it) the backspace key causes a control H (^H) to be printed to the screen. When I am in vi, the backspace key actually backspaces.

When I dial in from work, I use a Hewlett Packard terminal and the hp2626 termcap. At the shell prompt, the backspace key backspaces and erases. In vi, it just backspaces. In fact, I am using the HP terminal now along with vi to compose this.

It would be nice if chameleon would at least actually backspace when I am at the shell prompt. It would be nice if it erased, too, but that is really not required. Does anyone know of any additions or deletions I can make to the chameleon termcap? I looked at the termcap manual page and the entry for the hp2626. I tried a few things but nothing worked.

Thanks.

TURBO BASIC

- is there a patch yet to correct the time functions for North
America? (I tried the one someone posted here before, no go)
- how do you load handlers with it?
- anybody got any notes on how it uses memory?

SPARTADOS

Thanks to all those who answered my questions on Spartados
and the US doubler... I bought it and am very pleased.

I would say this is the height of the art of Atari command line DOS's,
with batches, time/date stamp on files, and a few great utilities.

Now I need MORE utilities..anybody got a boot sector, high speed binary
loader? other goodies?

SUPERDOS

I got an 'incidental' copy of this DOS on a traded disk. I have not seen
it advertised... anyone know its origin? It has a high speed skew format
option. You need some additional hardware I guess, because it doesn't work
with the US doubler I have.

The interesting thing is, it works at high speed if you format with
Sparta/US doubler! You only have to copy sector 360 from an empty formatted
Atari DOS disk to your Sparta formatted disk, then you boot Superdos
and write it to the new disk (menu "H"). Then all reads and writes under
Superdos happen at high speed. That's great with Turbo basic, which you
can't use with Spartados (memory conflicts).

dick,
i don't use Turbo BASIC much since it doesn't work with
SPARTADOS, but when I first got TB (before I had SpartaDOS), I remember
that all I need to do to fix the clock program that came with it was to
change a divide by 50 to a divide by 60... granted this was just a call
to a time function... I can't remember if TB has a time$ function, but
I never messed with it...
another reason that I don't use it is that I have deep blue C,
and recently got the ACE C pd C compiler (an extension of dbc and/or
related to it via the original pd C compiler that John Palevich built
dbc from), and I have Kyan Pascal... all of which work with SpartaDOS.
Kyan Pascal also comes with an excellent macro assembler, a real nice
program editor (the only thing it doesn't have is some sort of tabbing,
but that is understandable since you only have a 40 column screen to work
with), AND a neat little mini-Unix environment called KIX that runs
right on top of DOS 2.5 or SPARTADOS with ls, rm, mv, etc. and limited
redirection capability (e.g., ls *.* > file)... well worth the $70.
The pascal compiler is ISO with support for Atari graphics and sound...
I would recommend that you get your hands on dbc or ACE C and
build your own tools... (this is particularly pleasant if you have a

ramdisk to work from).

Body handling: HTML body converted to readable text

food for the line eater ???

I thought I had posted this last week, but we have had a queue problem...
(I wondered why I never saw these docs come up in the group!) So here
they are again:

here are the docs for the pd vt100 emulator for the 8-bits...
i debated about posting this as is rather than 'compress'ing it on our
Unix system, and then uuencoding it there..., but i figured that
some of you may not have 'compress' and 'uudecode' on your unix systems,
so here it is.

it would be good to get some idea about how many of us in the 8bit
group have :

1) uuencode & decode on our:
a) unix systems
b) 8bits
2) arc & arc11 for the 8bits
(which i posted recently)
3) compress & uncompress on our unix systems
4) are NOT on a Unix system...

if you all would like to send me mail telling me about your net
access environment, I would be willing to compile this info, and
post a summary to the group. (i hope it's not going to overflow my
mailbox!)

****

VT-10-Squared Terminal Emulator Instructions

****

Version 0.7 adds some VT-100 features and corrects some bugs
in order to facilitate operation with UNIX and the vi editor.
It also adds a capability to transmit even or odd parity.

This version of VT-10-Squared operates at either 300 or 1200
baud, and will also operate with the ATARI 835 and 1050
modems (thanks to the Russ Wetmore/Joe Miller R.BIN, and some
consulting from Russ) as well as with the 850 interface
module.

VT-10-Squared emulates a limited, but basic, set of VT-100 functions. It provides a full 80-column screen by use of a software handler which uses a 3-pixel-wide character set. While the characters are not perfect, you will find them quite readable on a crisp monitor or black-and-white TV.

VT-10-Squared requires:

Atari 400/800 with 24 K (requires the translator disk when used with the XL's).
DOS 2.0-compatible disk drive
850 interface module and 300- or 1200-baud modem
OR
835 or 1030 modem
OR
A (compatibile) non-Atari handler--requires a special VT-10-Squared file called VT10NH.XMO
A 'good' monitor

Two different keypad layouts are provided; one is patterned after the normal DEC VT-100 keypad, and the other is tailored for use with IBM's PROFS office automation software. You will probably want to use the DEC keyboard, but read the descriptions and decide for yourself!

VT-10-Squared does not support all VT-100 capability, particularly special graphics characters, special character sizes, and 132-column screen. As a result, it will not work properly with some DEC products.

GENERATING A WORKING DISK FOR ATARI 850, 835, or 1030.
Download the file VT10SQ.XMO using Xmodem transfer protocol. This file should be renamed AUTORUN.SYS. DOS 2.0 must be on the same disk. This single file contains two handlers (for comm. and for the 80-column screen) as well as the main communication program.

GENERATING A WORKING DISK FOR NON-ATARI HANDLERS.
Download the file VT10NH.XMO using Xmodem transfer protocol. This file *does not* have any comm. handler, but only the 80-column handler and the main communication program. With some non-Atari handlers, the next step is to name *your* comm. handler AUTORUN.SYS. Then append the VT10NH.XMO to the AUTORUN.SYS file (C - copy - VT10NH.XMO to AUTORUN.SYS/A using DOS 2.0). If this works, great. If not, you're on your own!

LOADING AND STARTUP.
The disk produced above is self-booting. DOS 2.0 loads the three pieces (comm. handler, 80-col. handler, and emulator), and install the two handlers. After the program is booted, a title screen appears, followed by a setup menu. The setup menu permits choice of 300- or 1200-baud (not available for

835/1030), choice of parity (none, even, or odd), and choice of the DEC or PROFS keypad layout (see description below).

When the setup is satisfactory, pressing begins communication. If you're using the 850, start typing! (Setup your modem, or whatever.) If you're using an 835 or 1030, a new screen will appear so that you can type in the number to be dialed. All non-numerical entries are ignored (spaces, hyphens, etc.). Pressing will abort dialing.
Pressing will also hang up the phone when you are finished.

Don't forget to have your 850, 835, or 1030 or non-Atari device turned on *before* booting VT-10-Squared. There are no error messages!

If you run across any problems, let me know.

-Dave Bailey [71635,1034]

****

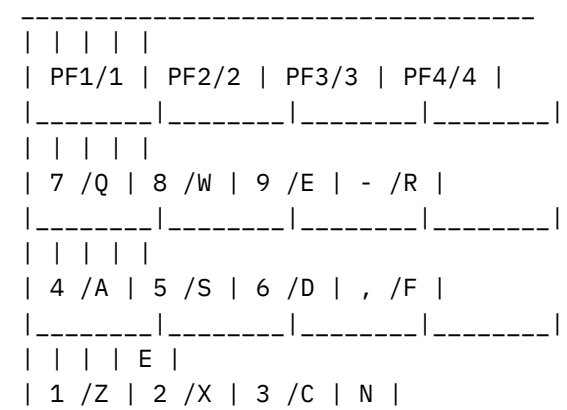
VT-10-Squared DEC keypad configuration

****
The 'DEC' keyboard functions are shown below. This keyboard arrangement is intended to bear a reasonable similarity to the VT100 layout, so that keypad functions can be translated with a minimum of pain.

Entries on the DEC keypad are made using a sequence, where is shown below in the right-hand cell of the VT100 keypad illustration. As an alternative, the keypad entry may be made using the key as a shift key.

Of course, these two-character sequences apply only when the keypad is in 'Keypad Application Mode', and not for normal numeric entry.

VT100/ATARI



```
|________|________|________| T /V |
| | | E |
| 0 /B | . /N | R |
|_________________|________|________|
```

Additional VT100 keyboard entries are as follows:

VT100 ATARI

Backspace

Delete

Escape

Line Feed (Logo)

Grave Accent

Tilde

Left Brace

Right Brace

Cursor control is the normal ATARI .

****

VT-10-Squared PROFS keypad configuration

****

Note: PROFS is an Office Automation program which runs on IBM mainframes under VM/CMS. It is designed to work with an IBM 3270 terminal. There is a protocol converter which runs on a IBM Series 1 minicomputer connected as a front-end to the mainframe which allows VT100 terminals (among others) to use PROFS. Since this protocol converters was first developed at Yale University, it is known by that name.

The following ATARI key sequences are used to represent the equivalent VT100/3270 keys:

Yale Protocol ATARI VT100 keypad Xmitted
Converter Sequence

PF1 <1> PF1

PF2 <2> PF2
PF3 <3> PF3
PF4 <4> 7
PF5 <5> 8
PF6 <6> 9
PF7 <7> 4
PF8 <8> 5

PF9 <9> 6
PF10 <0> 1
PF11 2
PF12 3
PA1 PF4
PA2 -
PA3 ,
NA 0

NEWLINE RETURN <^M>
ENTER (Logo) LF <^J>
CLEAR ENTER
FIELD TAB <^I>
DELETE ($7F)
ERASE EOF
TOGGLE INSERT .
HOME <^H>
RE-DISPLAY <^V>
Escape
Grave Accent <$60>
Tilde <$7E>
Left Brace <$7B>
Right Brace <$7D>

As an alternative, all of the two-key sequences beginning

with can also be accomplished by using the key
as a shift key. (E. g., depressing <1> while holding down the
key will transmit the equivalent of PF1.

From: KUYLMAN@HLERUL5.BITNET.UUCP
Message-ID: <8703041820.AA06143@ucbvax.Berkeley.EDU>
Source record: 117765

Dear everybody,
I have a Happy compatible board in my 1050 drive, and I have some
DOS systems that can format double density, but I would like to know
the SIO or CIO commands to do that from a machine language program.
I have De Re Atari and the technical reference manuals, so I know how
to format single density.
Does anybody have information about how to do this?
Please post this to the net, I think there are more people interested
in this.
Thanks anyway,
Frits

I don't have any connections to ANTIC but I should be getting my issue in
2 to 3 weeks (subscribers get them faster). I'll post info as soon as I
get it. I, too, am excited at the prospect. I was disappointed that EPYX
didn't come out with an 8 bit version. Someone on the net a couple of years
ago said they had written an 8 bit version. They never posted it. (A wise
decision, I'm sure since EPYX owns the right to it). I imagine that EPYX
would have had to give their approval to ANTIC before it could be published.
I just hope it comes close to the ST version.

The following article and answer from Neil Harris of Atari was carried
in the ST newsgroup. Since many readers here do not read the ST group
and since I knew it would be of interest to all 8-bit owners, I am
reposting it to this group. It is good to see that Atari is still
committed to the 8-bit owners, especially with software. But I'd love to
see the release of the 3.5" disk drive.

> supporting the ST line.
>
> So when are we going to see some real support for the 8-bits???

You asked for it...

Just a few hours ago, I talked to Alex about 8-bit support. He will be
spending quite a bit of time in the GEnie 8-bit conference (called "ATARI").
It will take him a little while to wade through all the messages there
already, but expect to see his presence there on a daily basis.

A further note. I had a meeting last week with TOP management here at
Atari. The topic was also 8-bit support, including ways to get software
produced by outside companies and how to get better presence for 8-bit
software. The subject has yet to be concluded, but we are coming up with
some good ideas.

>
> Thanks,
>
> Dan Boskovich

Yes, you'll need a terminal emulator in order to use an editor. All
the modem does is send signals between two computers, it does not
perform any terminal emulation.

I mainly use Chameleon (I think I spelled it right) for working on
mainframes. It is available from ANTIC for $19.95. It also includes
a .termcap for use with the vt-52xl's extended codes.

I've been using Chameloen for about 4 months, and I've been extermly
satisfied with its emulation and file transfers.

I think you will not find a program which satisfies all your wants, but I must
```

join John Sangster in heartily recommending the Omniview board ($50) from CDY computing. I am currently using Omniterm ($10?) on a unix system with vi to compose this message. It also works just fine with Gnu emacs. I run it at 2400 baud, although it is only claimed to work at 1200. (on rare occasions, I get a buffer overflow with emacs, which refuses to understand xon/xoff, but this is not a serious problem.) It gives you both kermit and x-modem, although no ascii capture. The emulation is vt100. Not everything is emulated, but enough to edit and play rogue. (For example, there are no double height/width characters.) It takes about 10 minutes with no soldering to install. My only complaint is that the character set is Atari's, meaning that curly braces, tildes, etc. show up as funny characters. You can generate them from the keyboard. Maybe David Young will come to his senses some day and fix this. The board is a piggyback on the OS board, so it doesn't take up a slot. You can use 80 columns for anything which uses E: or S:. One potential problem: Omniterm and Omniwriter (the word processor which comes with Omniview) won't run with DOS XL. I had to buy MyDos to use them with my double density Percoms. (of course they work fine with Atari DOS.) Imagine, an Atari DOS with subdirectories. Why did no onw ever tell me?

I too, am interested in the 800/dinosaur version of Turbo Basic. Perhaps whoever has it could post it to the net, as there seem to be several people interested.

> GEnie:M.APPELBAUM

Sorry, no. Setting Chameleon to RUBOUT will cause it to transmit a delete
character ($7F) instead of backspace ($08). This will not fix the problem
Charlie Dennett asks about: now the shell will interrupt commands when
backspace (now delete) is pressed and vi will stop working.

The problem probably has to do with what character the system thinks is
the 'current' erase character. Type in 'stty' to the shell and you
should get output similar to this:

speed 9600 baud; evenp hupcl
erase = #; swtch = ^`;
brkint -inpck icrnl onlcr
echo echoe echok

By default, the UNIX Operating System uses the '#' character as
the erase character. Unless this is changed in your .profile (or
the system /etc/profile), then the shell will be expecting '#' as
the 'backspace' character. Thus when it sees '^H' it assumes you
really want to enter a '^H' into the command.

To correct this, type this command to the shell:

stty erase ^H

(^H is one keystroke - ok?)

This should fix your problem. If it does, put the above command
into your .profile so it gets executed every time you log in.

PS. the stty command will also show you what character are currently
the interrupt, quit, kill, end-of-file, end-of-line, and switch
commands. Having these messed up is a good way of getting very
confused, fast. (A better way is to mess up the stty so that the
system does not echo back the characters you type. Ouch.)

269. Atari EXPO

Newsgroup: comp.sys.atari.8bit
Date: 1987-03-05 14:53:29 UTC
From: appelbau@topaz.UUCP
Message-ID: <9860@topaz.RUTGERS.EDU>
Source record: 117773
Cross-posted to: comp.sys.atari.st,comp.sys.atari.8bit

The Eastern Pennsylvania ATARI EXPO will be held in Allentown, Pa., on Saturday, March 14th (10am to 6pm) and Sunday March 15th (11am to 5pm). The show will be at the Hilton Convention Center, 9th & Hamilton Streets.

Here is a list of some of the companies that are attending:

Alpha Systems
ANALOG Computing
Atari Corporation
Atari Explorer
Best Electronics
Cal Com, Inc.
Disk Publications, Inc.
Hybrid Arts
ICD, Inc.
J&S Computers
Michtron
Microdraft
Quantum Microsystems, Inc.
Zobian Controls

and many more.

The special guest will be Bill Wilkinson, V.P. of OSS, Inc.

Tickets are $5.00 at the door. For more info call:215-837-1046

Well I must say that I'm impressed with the amount of support on GEnie, in both the ST and ATARI roundtables. I've been really impressed by Alex Leavans. He seems to know a great deal about both lines of computers. It looks like we will be seeing some great things coming out of Sunnyvale for both the ST and 8bit.

It seems that Neil really does listen to us, even when we complain.

What to go ATARI!

ATDT# is a Hayes modem command, which means that you have a Hayes compatable modem. This is the industry standard in modems, so you should be able to find someone with a Hayes who can give you a copy of the command list.

If your modem hooks up to the 850 interface, then any good telecom program (I use HomeTerm) should work fine.

The XEP80 is almost ready, along with special versions of Silent Butler and
Atariwriter + which will take advantage of the 80 column card. We are also
readying BattleZone XE, a version of the popular arcade game. The SX212,
our 1200 baud modem, will plug directly into the SIO port on your 8 bit,
in addition to being able to be used by the 850 interface and clones (ape-face,
P:R:Connection). As for the 3.5" drive, wait 'till summer CES (1st week in
June), I think you'll be very nicely surprised. <smile>

Source record: 117794

In answer to Michael Farkas's question about making an 800XL emulate a disk drive, I would suggest the Newell 256KXL board and OMNIVIEW256. The 256KXL is a small logic circuit which figures out what signal to put on the single extra pin that is needed to control a 256K Dynamic RAM chip instead of the standard 64K ones in an unmodified XL. You remove the 8 64K-bit chips, replace them with 8 256K-bit chips (which can be purchased with the 256KXL board), and solder up about six or seven wires to strategic places on the main board, and presto-chango, you now have a 256K machine. Then you replace the standard Atari O/S chip with OMNIVIEW, put the case back together and fire it up. Press "1", then hold down START and press RESET, and suddenly you have an invisible, blindingly fast extra disk drive called D1:, which works just like a normal one except about maybe 50 times as fast. If you prefer, you can set it up as D2: or whatever, but it is especially handy if you put DUP.SYS and your favorite application programs on the RAMdisk, because then switching programs is almost instantaneous. The RAMdisk can be activated also under software control, and CDY gives instructions for how to do that and supplies a short 1-sector machine language program for this purpose.

Of course, putting in OMNIVIEW also gives you 80-column display capability, makes the Translator disk unnecessary, and gets you CDY's OmniWriter 80-column word processor thrown in free, as well as giving you compatibility with the very nice OmniCom VT100 emulator, which CDY also sells (for $10 I believe).

Also, MYDOS is thrown in with the 256KXL board. And by the way, you can run the 256KXL as a "double sided" drive, i.e. with twice the capacity of a normal drive, about 1500 sectors as I recall. Another trick you can do is to use the RAMdisk handler provided with MYDOS to install the standard 499-sector (formatted) 130XE RAMdisk and AT THE SAME TIME you can run a standard 708-sector (formatted) full-sized RAMdisk. I've done it, and it is sometimes very convenient to have two independent RAMdisks!!!

When you consider the cost of a second disk drive ($125 plus shipping if you really shop around), and the speed of operation and the eventual wearout of the physical drive, versus the high speed, zero wear, 80 columns, and free 80-column word processor you get going with the RAMdisk, for less money at that, it isn't hard to decide in favor of the RAMdisk!!!

You'll have to experience it yourself to understand, but all of a sudden, switching from DOS to an application program (or BASIC) and back goes so fast you think you are on a VAX or something. All I can say is "Go for it!"

CDY can be reached at (214) 235-2146 or by mail at 421 Hanbee, Richardson TX 75080. Newell Industries can be reached at 602 E. Hwy 78, Wylie TX 75098. CDY is, by the way, a dealer for the Newell board, so you can order both products (as well as OmniCom) from CDY. I don't know if Newell also sells the CDY products.

-John Sangster/jhs@mitre-bedford.arpa

I am not associated with either company other than as a customer of CDY.

I am getting ready to buy a 1050 disk drive for my 800XL. One the mail-order ads in ANALOG Computing says that they include DOS 2.5 with the drive, another says they include DOS 3.0, and the rest are silent on the topic. Some questions:

1. Does DOS always come with the 1050 or are those two firms actually providing something special?

2. If I have a choice (and it seems that I do), which DOS should I get and why? (I know that newer does not necessarily mean "better".)

3. Are there any other versions of DOS that I might want to use?

4. If I buy the drive that comes with DOS 2.5 (because it's cheaper), can I *legally* make a copy of someone else's DOS 3.0 and use it?

Thanks for the info.

I would strongly recommend that you use DOS 2.5. It is the latest and greatest from Atari. It is an improved version of DOS 2.0S. DOS 3.0 is an aberration and is non-compatible with DOS 2.0/2.5. DOS 3.0 is more or less abandoned by Atari and most users. DOS 2.5 disks have a file on them that will translate DOS 3.0 file to DOS 2.5/2.0S.

There once was a DOS 2.5D for an 815 double density drive -- neither the drive nor the software was ever available to the public. [Yes, I know that some were built and did get out, but Atari essentially yanked the plug before public sales happened.] However, several companies took DOS 2.0D and modified it for commercial purposes. I believe that this is the origin of both MYDOS and SpartaDOS. Both are available by themselves as well as with various upgrade kits, etc. Both allow for mulitiple disk drives (5.25 and 3.5) and hard disks. I personally have only tried MYDOS -- it would not run ANTIC magazine' disks, so I did not try to use it further and stuck with DOS 2.5. However, if you want a truly double density disk drive, you must use either MYDOS or SpartaDOS. (As opposed to the so called double density of the 1050, which is really an enhanced density, more like 1 1/2 density). Personally I stick to straight vanilla 1050 drives, they can be upgraded to true double density, however, with the USDoubler (which also includes SpartaDOS, I think.) And if you upgrade to 256k with a Newell upgrade, you get MYDOS free. CDYoung Associates (CDY anyway) sells various software and hardware updates. J Sangster will probably

tell you about them. To answer you last question, some form of Atari DOS comes with every 1050, they are not including something extra. 1050 drives first came with DOS 3.0, newer ones come with DOS 2.5. (Very early ones may have come with DOS 2.0S.) Finally, between DOS 3.0 and DOS 2.5, another version was created by the pre-Tramiel Atari Inc. (as opposed to Atari Corp.) which was called DOS 4.0. It is available from ANTIC magazine, I am not familar with it except to know that it was being developed for several new Atari computers that were stillborn (i.e. they died before being released, similar to the 815 dd). I think that 4.0 was for the 1450XLD model. Other models not released were the 1400XL and 1600XL, although the latter was not even ever announced to the best of my knowledge. Both the 1400XL and the 1450XLD were announced and advertised, but still died.

296. Rana 1000 Disk Drive

Newsgroup: comp.sys.atari.8bit
Date: 1987-03-13 18:48:45 UTC
From: tom@felix.UUCP
Message-ID: <2418@felix.UUCP>
Source record: 117800

Greetings,
I just purchased an Atari 800 with a Rana 1000 disk drive.
They have been unused and are in perfect condition (circa June, 1983).

The Rana manual says they the drive only supports single density with
it's firmware, but double density supporting firmware is coming. Did it?
It appears that Rana Systems is no longer in Chatsworth, Calif.
Does anyone know where they are or how I can get a copy of the firmware?
I assume the DOS 2.? I have doesn't support double density anyway.
What's the latest OS and where is a good place to get it?
Or am I a few years late?

Thanks,
--

absolutely what marc says... dos 3.0 was a big mistake on atari's part...
among its many features: incompatibility with dos 2.x disks...
dos 2.5 is your best bet for 1050 based systems..., but if you really
want a thrill, go to your local atari dealer, and ask him to install
a usdoubler in your 1050... usdoubler is made by icd out of chicago, and
it is an excellent hardware improvement... by itself, the doubler doesn't
changer your life at all, but with icd's spartados you enter the big
leagues... among the usdoubler/spartados many features are:

1) transparent compatibility with any disk format
2) very well done msdos-like command line dos with
file time/date stamping
3) spartados is also compatible with hard disk drives

one catch: you really need an xl/xe machine to enjoy all that spartados
has to offer... i almost forgot, the usdoubler chipset in a 1050 gives you
true double density capability, and double or triple the speed on disk i/o.

What I am looking for is not a ram-disk, but rather a machine that
actually thinks it is a disk drive and, when other Atari's try
to access it through the atari serial interface, they also think that
it is a disk drive. My objective is to network several Atari computers,
using a supra micronet, and have this chunk of memory available to all
of them.
I am also looking for a copy of the article on the XL parallel bus
interface from the Feb '85 issue of ANTIC. Any help will be greatly
appreciated.

DOS always comes (well, it should) with all units coming from Atari, and the version should be 2.5.

>2. If I have a choice (and it seems that I do), which DOS should I get
> and why? (I know that newer does not necessarily mean "better".)

Get DOS 2.5. You do *NOT* (I repeat _not_) want version 3.0. Even though the old Atari had good intentions when it wrote this poor program, it is now quite a huge pain-in-the-booty. It is _not_ compatible with the older versions of DOS and not compatible with other third-party DOSs as well.

>3. Are there any other versions of DOS that I might want to use?

I would strongly recommend SpartaDOS from ICD. You might also want to purchase the US Doubler chip from ICD as well, which jumps your standard drive speed by a factor of 3 (300% faster) However, SpartaDOS will work with an unmodified 1050 drive. (The US Doubler itself is a chip enhancement which is installed in your 1050)

>4. If I buy the drive that comes with DOS 2.5 (because it's cheaper),
> can I *legally* make a copy of someone else's DOS 3.0 and use it?
>

Well, I am not sure if DOS 3.0 is PD or not, but I really do not think Atari Corp. will care if you do, considering there is _no_ commercial software that supports or comes with 3.0.

A good reason to avoid 3.0 is this: all other versions of DOS written by Atari format the disk in 128 byte sectors. 3.0 uses a 1024 byte sector routine. So, if you were to, say, write a file that is 1025 bytes long, 3.0 will force the use of two sectors, resulting in the loss of 1023 bytes on your disk (which would be trivial on other systems but since 3.0 can only put ~90,000 bytes on a disk, this eats room FAST.

Good to be talking about the 8bits again even though I have been concentrating on my ST since I bought it last October.

I am going to disagree with you on this one. DOS 3 was in many ways a superior DOS to DOS2.5 or DOS2.0. Both 2.5 and 2.0 have the following annoying problems:

1. When you open a file for appending, DOS 2.5 and 2.0 both "round" up to the next sector before they begin writing. In a business program (who uses there Atari for business, me thats who!) I wrote, I appended 17 byte records to the end of a transaction file. The actual filesize increased by a full 128 byte sector however. DOS III does the right thing, adding it directly to the end of the file.

2. Note and Point are both screwy on DOS 2.0 and 2.5. They return the actual PHYSICAL sector and byte number that the head is positoned at. If you implement random access files by maintaining a table, you have two problems. If you copy the file you need to remake the pointer table, and you HAVE to maintain a table. Under DOS 3.0, note and point return LOGICAL addresses from THE BEGINNING OF THE FILE. Now, it is relatively easy to find any record, and files may be copied at whim.

It is a pity that 3.0 wasn't a bigger success. It really is a superior DOS to 2.5. 2.5 never fixed any of the design flaws of 2.0, it only slightly modified it to run with higher density drives.

I can't really recommend you use DOS 3.0, it is incredibly non-standard. I like it alot however, and it offers certain things that have been useful on several projects. My brother uses MYDOS alot, and swears by it.

Has anyone used DOS 4.0? I am interested in hearing about it? Does it suffer from the 2.0 -- 2.5 problems?

Atari 2.0 does the same thing, except with a finer granularity.
DOS 3.0 kills you if you have lots of teensy files, but really
doesn't hurt much otherwise. If you combine that with the
append bug that I mentioned in an earlier article, it really
gets bad. I have wasted far more space with the append bug than
any other problem.

By all means, use spartados if you have a doubler. Use MYDOS or
2.5 if you need 2.0 compatibility. I still use 3.0 for most of
my programming, and have suffered no ill effects. It really
isn't all that bad.

Long life to the 8-bit users!

ATTENTION TO ALL THOSE WHO THINK THE ATARI NEEDS MORE SOFTWARE!!!!!!!!!!!

I would like to know why such games as Gunship (Microprose), Bard's
Tale I and II (Electronic Arts), Defender of the Crown (Cinemaware), PHM
Pegasus (Electronic Arts) etc., etc., are not available for the 8-bit Atari!
I am very anxious to purchase software of this calibre but it is very
difficult if it is not made for your machine. If someone from any of these
software companies is listening I would like to see an answer to my
question.
There are a lot of 8-bit owners here in Nova Scotia who would
like to see these games on the market for our machines. Why does the
Commodore 64 get so much attention and the Atari 8-bit get left behind? These
are questions which the software companies must start thinking about. There
are a lot of honest Atari owners which, I hope, the software companies will
hear from. So, those of you who have seen a game advertised and wondered
why the caption said C-64 but not Atari 8-bit speak up and let those software
companies know that you want some good quality software!!!!!!!!!!!!!

DOS 2.5 is better, because it is more compatible.

> 3. Are there any other versions of DOS that I might want to use?

I like OSS's DOS XL, but I don't think that supports the
higher density in the 1050. I like DOS XL because it's a command
line interface, rather than a menu style.

I have had a request for Ace C, of which I own a copy. I obtained mine for $5 by answering a classified ad in Info-World, from an address which I con't remember. There are no copywrite notices on the documentation or the disk.

Does anyone know whether this is public domain software? If it is, and there is sufficient interest, I can post it. In the meantime I will write to the author about the legal status. It seems to be a revision of Deep Blue C, and J. Palevich still appears as one author.

I've found Gunship for the 8-bit Atari. The next time you go looking for atari software browse through the commodore section. Sometimes, the software will be written for both atari and commodore but is put in the commodore. But overall, I agree, the 8-bit atari is being left behind in the availability of new software. I would like to purchase some of the flight simulators that are only available at present for the commodore. I've thought about purchasing a commodore just to be able to buy new software again, like the good ole days when atari was more popular and the 800 series was still being manufactured.

309. OMNIVIEW compatibility

Newsgroup: comp.sys.atari.8bit
Date: 1987-03-17 19:47:04 UTC
From: njd@ihlpm.ATT.COM
Message-ID: <1013@ihlpm.ATT.COM>
Source record: 117713

Greetings all you 8-bit fans,

I FINALLY got OMNIVIEW XL/XE installed in a 130XE. (This was my second XE; I destroyed the first one with my ham-handed attempt to install a RAMROD board myself; this time, I started with a new machine, the old one being beyond reasonable repair [est. $110 to $120], and REX TV Service socketed the chip for me, for the cost of the socket only [of course it was a $3.50 socket, but I'm not gonna complain!!].)

I have run some simple functional and "compatibilty" testing on it and have a couple of comments.

First, I was pleasanly surprised by the following: The manual states that OMNIVIEW should work with any DOS that doesn't hide "underneath the cartridge" or OS [ROM address space, a/k/a the upper? 16K of an 800XL for one]. Well, I had thought this meant that I wouldn't be able to run DOS XL in the "S" (Supercartridge) or "X" (XL/XE machine) extended mode, because it does just what the manual is talking about (as I interpret it). I tried it anyway just to see what would happen. I booted up my 130XE with OPTION depressed, which running OMNIVIEW, causes BASIC to come up (great if you don't use BASIC a lot, like me). DOS XL came up happy as a clam. I typed CAR to get to BASIC, and then hit <CTRL A> RESET to switch to 80 columns. No problem. (By the way, I don't have the Commodore cable that came with my 1802 monitor fixed up [w/a 5-pin DIN plug, I hope it will work] yet, so I'm "seeing" composite color. I was able to read the display amazingly well, despite the low-res. monitor mode and red smudges from artifacting. I also like the dual-background-color feature, the text colors have been chosen well.)

Then, I hit RESET to switch back to 40 columns; no problem. Now, back to DOS XL. I hit <CTRL A> RESET again, and there I was talking to DOS XL in 80 columns. I hadn't even expected 80 columns to work with BASIC, given that I am running DOS XL in "X" mode (stuffs itself into the 16K given that I was running DOS 2.30[?]X [i.e. renamed DOSXL.XL to DOSXL.SYS when I set up my DOS boot disk]), and therefore was violating what the manual says! Whether I am somewhat ignorant of the truth behind the docs. or whatever, I am very happy with this beastie so far.

I have only found one piece of commercial s/w in my small collection that barfs on my "130XEO" (how's that for shorthand?), and that is the word processor that a nice s/w store owner sold me a couple? of years ago, Datasoft's "Letter Wizard." I really

don't care, because I am going to switch to using OmniWriter which came with OMNIVIEW, but my wife was a bit upset (she has been using L. Wiz. more often than ever lately). I offered to convert her files for her, but it looks like she will be playing "musical computers" with my "old" 800XL (SIO A/B switch, anyone?)

I haven't tried a couple of relatively unimportant programs yet, namely Flight Simulator II which I can't land without a death-defying adventure (I'm not a power pilot anyway, I fly sailplanes [gliders w/long wings]), and a game I bought "long ago" that I never play ("The Eidolon" is much more fun, especially since I got it at Toys R Us for $10. How do they do it? Mine them from a hole in the ground?).

If I notice anything worth commenting on when I try OmniWriter and OmniCom (I can hardly wait), I'll post another article. (Actually, I see that I'm going to miss "snapshot" [capture], I've been using [old APX] Chameleon for a long time! I tried JHP's Kermit + VT52, and ACSTERM, but there's nothing like 80 columns for editing/more-ing etc. on UNIX!)

Sorry if this article is too long for your tastes. (I was born with a hard-coded "-v" option!)

Nick (no more desoldering chips from computer PC boards for me) DiMasi

310. Atari XM301 modem problems

Newsgroup: comp.sys.atari.8bit
Date: 1987-03-17 20:39:40 UTC
From: euloth@dalcsug.UUCP
Message-ID: <21@dalcsug.UUCP>
Source record: 117714

I own an Atari XM301 modem and am very disappointed with the documentation for it! I am trying to write a BBS program for my machine but I am getting stopped constantly by problems dealing with the modem. The technical reference notes may be informative to someone who has been programming with modems for some time but for a seasoned programmer who has never used a modem with anything other than applications software it is very difficult to understand. I dug up an article on the 1030 modem which helped quite a bit but I am still having problems.
The major problems I am encountering right now are: 1) it doesn't want to send Atascii eol's; they are being translated to esc's. I have a feeling that this is the effect of having the high bit (bit 7) being set to 0 on input data. and 2) the suspend and resume commands don't seem to work (maybe -- or should I say probably -- I am doing something wrong). I tell the modem to go into suspend mode...read part of a file from the disk...try to resume modem operations and I get an error 136 - device not present or some such strange thing. It doesn't want to work for me for some reason.
If there is someone out there who can set me off and running with a competent set of instructions and a good set of explanations for a layman please post some info - maybe someone else might like to know about it.
Or send me email to euloth@dal.uucp (I think..I am a little new at this nationwide email service.) Thanks, in advance!

Glenn Euloth

311. DOS's

312. Atari: We'd like to hear from you.

Newsgroup: comp.sys.atari.8bit
Date: 1987-03-18 06:56:16 UTC
From: akw@osupyr.UUCP
Message-ID: <112@osupyr.UUCP>
Source record: 117716

Since I haven't heard a whole lot from Alex and the gang from Mt. Fuji,
I'd like to put some questions/statements up for grabs.

New products:

The XEP-80:

What is the expected date of shipment on this? We heard about
this device nearly a year ago but no word from Atari. It's too bad that
the "old" Atari didn't put some sort of 80-column mode in the XLs (or the
"new" Atari in the XEs) when they first came out.

Such a bruhaha was made about compatibility with old programs.
Folks, lets look at the Apple //e, //c and][gs. The][and the][+
didn't have any sort of 'stock' 80-column boards, only the ones by
Videx and the like. But when Apple got smart and decided to put a
serious textual display on their micro, software simply was written
for the new hardware. Granted upgrades were somewhat offered to the
old owners (through buying third party boards or buying a //e,c) but
the machine still lives on, with much software.

Now: why can't we have a new XEE (for lack of any other name)
that would be an enhanced XE with built-in 80 column hardware on the
motherboard, with either output on the 5pin DIN or a separate RGB port
out the back? Sure, in the eyes of some this might be too little too
late, but I know for a fact that here in Columbus, Ataris are still
selling like they were in '82-'83 when I bought my 400.

SX-212:

Shame, Atari. A modem. It didn't even take, oh, 6 months after the
XM301 was introduced that it hit market. It wasn't much, but it was small,
cheap and quite fun to use. Why is it taking so long to get a modem to
market? This, however, is not such a point since there are so many
other modems to choose from.

XE Game System:

No, 8bitters, this is NOT a crack on the integrity of our
machine. Even though I currently use an ST as my main machine, I recogize
the 400/800/XL/XE as the de facto 8 bit micro -- years ahead of the Apples
and much nicer than the Vic/64/128. No, this "XE Game System" is what
I saw off of a 8 1/2 x 11 glossy advertisment/blurb a friend obtained.
It includes a "game unit" with four control buttons (read that: reset, option,
select, start), joyports (including a joystick and a light-pistol a'la
Nintendo or Sega home system) cart port (compatible with current 8-bit port)
and an (optional?) separated keyboard.

According to my friend Atari will still sell the XEs but this is directed at a 'different market.' Hmm... I think that I would have been much happier seeing Atari introduce something like this:

Atari 520 XP - the Professional 8 bit micro

512K RAM ... standard serial/parallel/scsi ports ... 2 game ports ... Integrated CPU box/disk drive (5.25 or 3.5in or both) with separated keyboard ... slots a'la Atari 800 ... 80 column 16- or 32-color RGB mode ... fully compatible (upward) with all existing XL/XE software hardware (include the silly Atari SIO for compatibility) ... XP Software including AtariWorkstation, an integrated WP/database/spreadsheet/comm package like MS Works for the Mac ... a desktop oriented DOS (5.0?) with MOUSE input

...just to name a few features (except for the price:) under $300

(goodbye C128 and A500)

Ah, but to dream. But, Alex/Neil/Landon and gang, this is what the 8 bits deserve. I mean, the graphics chipset is superior than that in the ST (not a flame, just a fact). The exterior of the 8bits should somewhat resemble the interior: slick, sporty, sweet.

A last plea: please don't turn it into the 2600 II.

(It's finals week at OSU and I am blowing off studying.... *yawn*.)

314. Engineering Symbols on Panasonic Printer

Newsgroup: comp.sys.atari.8bit
Date: 1987-03-18 18:23:19 UTC
From: cbz@mhuxu.UUCP
Message-ID: <6396@mhuxu.UUCP>
Source record: 117718
Cross-posted to: comp.sys.atari.8bit,comp.sys.atari.st

I have finally gotten around to writing a "print filter" which
allows my Panasonic KX-P1080 printer to print engineering (read
Greek) symbols through my Habawriter wordprocessor software. If
anyone wants a copy of the filter file let me know. If you don't
have the Habawriter wordprocessor you can still use these codes
to download the special symbols to your Panasonic printer.
The characters I have developed codes for are: big and little
sigma, mew, tau, infinity, alpha, pi, omega, beta, gamma, epsilon,
lamda, delta, angstroms, theta, phe, phi, pho and phum. (:^)

When I got my second 1050 last year, it came with DOS 3.0. I saw a note
here on the net that if you returned you DOS 3.0 disk to Atari, they
would send you DOS 2.5, unfortunately, they charged me $15 to send me
the DOS 2.5 manual. Get DOS 2.5 for an Atari DOS... for a 'real' dos,
I highly recommend SPARTADOS from ICD... it reads and writes just about
every disk format (transparently!!), except for DOS 2.5 which it (in the
latest release) reads all of, but can't write to the enhanced density
sectors of a DOS 2.5 enhanced format disk (it CAN write to the standard
sectors of an enhanced density disk.)

I would like to kow if anyone out there has an extra or trashed 800 keyboard that they would be willing to part with. I would like to find a supplier for those old keyboards but no luck yet.

Also, if anyone out there has an old Atari stuffed in a closet (probably eliminates most of us) and would like to free up some of that space please reply. Again I am searching for an 800 keyboard.

Does anyone know anything about robotic arms? I desire to have an arm for my spare 400 to play with. I would like to have a Microbot Mini-Mover-5 but I don't want to part with $600. I am considering modifying an Armatron after they come back down to $15.

I am looking for some expertise in this field...I cannot decide how to attain motion. Should I run cables? use hydraulics? pneumatics? put a separate motor at each joint? I really need some help.

thanks
Gene Merritt, a Pre-Mechanical Eng. student at Iowa State Univ.

From: "GENE MERRITT" <F1.GDM@ISUMVS.BITNET>

I have heard so much about CDY's OMNIVIEW upgrade that I went out
and bought one. I knew that I could get it for $39.95 COD but I
didn't want to wait for mail to get there and did not want to
call long distance...So I did the most practical, state-of-the-art
thing, I sent mail directly to David Young, via Bitnet.

This worked real well because I asked him a couple of questions
first and then after receiving the answers (via Bitnet) I decided
to order. This process took about a day, which is not bad for
sending two letters and replies each. I have had no problems with my
Omniview 256 except that the free terminal program, Omniterm, does not
work with my xm301...

This brings me to the real purpose of this posting. If XM301's have
been out for over a year now and have been fairly well received
then why do I have trouble finding programs that will work with it?

Every program that I want to use (except 1030 Express!, which I love
dearly) will not work with it without some hard-to-find T: handler.
This problem is further worsened by my desire to Telecommunicate in
80 columns with my new Omniview.

help!

Ralph Walden of Atari Club Enthusiasts in Eugene, Oregon is the other
author of ACE C. I believe that this particular version is in the
public domain. Ralph also has an improved version for the 130XE which
has a built in editor, faster linker, and all sorts of other goodies
which is shareware. (about $30 bucks is what he wanted last I checked,
although he has never made any money on this....) Try contacting him
via the Atari Club Enthusiasts, their address should be in Computer
Shopper, Antic, Analog, or any of the other Atari magazines...

Well, Ray, that would be nice but about the only place that carries Commodore software anymore is Zeller's. The Commodore "piracy racket" is so bad in Halifax (if not all of Canada.) is so bad that most computer stores refuse to carry Commodore software since they can't sell it! And Zeller's doesn't exactly have a good selection of Flippy disks. Thanks for the tip though.

Glenn.

```
An interesting problem:
----------------------
I added a Flash!(tm) disk drive enhancement to my Commodore 64 and 1541
disk drive years ago and have had no problem.... but then....
Recently I have added another 1541 disk drive and purchased the 2nd
Disk Flash and the error rate on data transfer shot WAY UP!
My old disk drive is the long-board model and the new one is a
short-board model with a lever to close the door instead of a flap.

The method:
----------
The method used by the Flash product is to utilize the
serial shift registers (which are unused) in the 6526 CIA chips
in both the 64 and 1541s. New operating ROMs in all machines essentially
redirect the data through new wires that are attached to pins on the chips
(across machines). There are only two lines and a ground to support the
data flow. One line is a sync (CNT), and the other is data (SR). The lines are
bidirectional - so the same serial shifter is capable of sending and
receiving. When attaching a second disk drive, the lines are hooked up
in parallel on the 64 side, so the same shift register
handles data transmission for both drives. According to the specs on the
6526 CIA chip in the 64 Reference Manual this is possible.
The two pins for the shift register are open-collector or open-emitter
(or some other technical term) which allows the shift register to drive more
than one device by simply daisy-chaining the devices.

The symptoms:
------------
However, the world is not perfect, and nothing is that simple.
Attaching the second disk's lines to the 64 cause errors at a rate of
about 1 in every 512 bytes. If I disconnect one drive (either one) then
there is are no errors in data transfer to or from the connected drive.
Only when both drives are attached, errors creep up suddenly. What is
worse is when both drives are connected but one is powered down:
Errors occur at a rate of about 1 in every 5 bytes from the powered up drive!!

The challenge:
-------------
I need help from a hardware-kind-a-guy who knows a little about
6500 series chips, preferably the 6526. I notice (according to the
64's schematic in the reference guide) that although the lines are not
used for the serial shift register in the 64, they are pulled up with
3.3Kohm resisters to +5 volts. Since the recommended method of
installation in the 1541 is to pry a 6526 pin out of its socket and connect
```

a wire to it, I know that there is no pull-up resistor on the 1541 side.
I wonder if this fact is causing a drain on the 64 side
whereby the 6526 cannot daisy-chain to more than one device. Or
is it possible that the 6526 chip in the 64 is defective?
What do you think could cause such a problem? I would be very
pleased to hear (via mail or news) any advice that could solve
this problem, since such a high error rate makes using the dual drives
unacceptable. Bryce Nesbitt (inventor of Flash) are YOU listening?

Thank you,
Scott McPhee

Well, the XEP80 is much closer now, we are hopefully going into production
on it sometime next month.

It took a bit longer than that for the XM301 to hit the market. The
SX212 is a much more sophisticated modem, and hence is taking longer to do.
BUt it should be coming reasonably soon now.

As a followup to the last note about Omniview, after spending
weeks trying to get vt10sq running (I kept thinking the problem
was with the UUencoded file), I discovered that my version
would run on a friend's unmodified 130XE, but not my 130XEO.

324. 8 bit hard disk question

Newsgroup: comp.sys.atari.8bit
Date: 1987-03-21 21:05:00 UTC
From: wrd@tekigm2.TEK.COM
Message-ID: <1576@tekigm2.TEK.COM>
Source record: 117728

Question: with either the Atari hard disk or the Supra harddisk for the 800/XL/XE series, can the hard drive be configured to be drive 1 such that it can be used for autobooting? Secondly, what DOS comes with the Atari hard disk for the 8bitter machines? A modified DOS 2.5 or what? And please, let's not get into another discussion over non-Atari DOS's, such as MYDOS or SpartaDOS.

Thanks in advance,

--Bill Dippert--

One source of keyboards for the Atari 800 is B&C Computervisions in
California. They carry all the replacement parts for Atari's including
complete boards, individual components and cables, etc. They are charging
$40 for the keyboard according to their Winter mailing list. This may
be more than you want to pay but if you are interested, call them
at (408)-749-1003. Hope this helps...

This is in reply to my own previously posted questions about Atari hard disk drives for the 8 bit line. I could have sworn that Atari announced a hard disk for the XE/XL/etc. computers and I was trying to get some information on it. In going over my A.N.A.L.O.G. and Antic magazines, I find no mention of any hard disk for the 8bitters from Atari, only from Supra. Can anyone from Atari confirm or deny an Atari 8bit hard disk?

Thanks in advance,
--Bill Dippert--

327. Re: Rana 1000 Disk Drive

From: store2@ihuxi.UUCP
Message-ID: <1572@ihuxi.ATT.COM>
Source record: 117734

I received the May issue of ANTIC yesterday. As promised, I wanted to give a little information on the Rogue game that is included with this issue. I have already started to type it in. It will be a few days before I am actually able to give a first hand report. The article says you need a minimum of 48K to play the game. It looks like it keeps track of health, food, weapons, etc. There are several levels (the article doesn't say how many) and you can save a game. When you reload it, though, it is wiped out so you can't use it as the starting point for several games although I suppose you could copy the file to another name and back again. It saves high score and uses a redefined character set for the graphics. It is credited to Robert Jung and is supposedly up on his BBS for on-line game playing. If you want to try before you type, call (213)-732-0229. That is in southern CA.

I will have the game up and running (barring any pesky bugs) in about a week and I'll report again. You use the keyboard only, no joystick. Single letters for commands and arrow keys for movement. If you are on CompuServe, ANTIC will probably make it available for downloading soon so you can save some typing effort. I'll try to review it completely enough to help you determine if it is worth the time and money to download it.

>
>An interesting problem:
[description of how either drive works alone, but how interconnected
drives fail, and a powered-off drive really mungs things.]

This seems like it's not too hard:

1.) When both drives are connected, the open-collector drivers in
one drive suddenly have to sink the current from not one but
two sets of pull-up resistors in order to pull the lines down
to logic 0.

2.) When one drive is off, its pull-up resistor is connected to
ground (or close enough); the lines can't be pulled up to
logic 1, and errors result.

Possible solutions:

1.) a.) Try disconnecting one set of pullups.
b.) Failing this, try increasing the current drain capability
of the line driver by buffering it, so that it can drive
the line even with multiple pullups connected.

2.) a.) Connect diodes (germanium, not silicon) in series with
the pullup resistors so that they can't sink current
when the drive is off.
b.) Don't try running with one drive off!

I have just recently received an atari 800xl from someone who said they
had no use for it. Not being one to look a gift horse in the mouth I
took it. All I have is the micro, no joy-sticks or drives. I just priced
a 1050 disk drive and it costs more than the micro did when new. I can't
seem to find a cassette drive for it but I've not been looking long.
I quess what my question for you atari owners is ... Is this worth pursuing?
Should I just try to find games and use it as a video game? How easy is it
find games and programs for the 800xl and how much do they run? Do any of
you have any technical info on it? Who has one and what has been your
experience with it?
Thanks ahead of time for any help you can give me.

Re: OMNIVIEW/VT10SQ compatibility. I normally run OMNIVIEW for all operations on my 800XL, and as I recall, I used vt10sq freely with it with no difficulties, switching to CDY's free OmniTerm program for downloading files, since VT10SQ does not support that sort of thing.

I don't know why a 130XE with OMNIVIEW should fail to work right with vt10sq. In fact, I would think you would have to run the TRANSLATOR DISK to get vt10sq to work at all with a standard 130XE but you would NOT need the translator disk to run it with OMNIVIEW. However, all of my OMNIVIEW experience has been with an 800XL with Newell 256KXL upgrade.

Source record: 117739

Calling all fellow Newell 256KXL board owners:

I have just completed figuring out how to patch a Newell 256KXL board so that it will act almost EXACTLY like a 130XE with respect to control of ANTIC. The patch should allow 256KXL owners to run graphically oriented software such as Xlent's Typesetter program and other "Desktop Publishing" applications without having to add the Newell-suggested manual switch "fix". In fact, I would expect it to run all commercial 130XE software exactly the same as a 130XE would, while allowing the extra 128K of memory to be used for a RAMdisk.

The patch requires cutting two foils and wiring up some unused sections of ICs already on the board, but it DOES NOT require adding any parts other than new wires. My guess is that it should take at most an hour or two to make the modification, given step-by-step instructions.

If anybody is interested in details when this patch has been fully tested, please let me know where I can mail info to you.

336. OMNIVIEW, UNIX, vi (HELP!), and misc. compatibility

Newsgroup: comp.sys.atari.8bit
Date: 1987-03-30 20:49:37 UTC
From: njd@ihlpm.UUCP
Message-ID: <1035@ihlpm.ATT.COM>
Source record: 117740

I have managed to get CDY's OmniCom (some call it Omniterm) VT100 emulator that uses his OMNIVIEW 80-column chip to work OK, except that I am having a problem. When I login to this UNIX system (essentially System V Rls 2.0, actually UTS 5.?.? on an Amdahl) and bring up vi, as soon as the editor clears the screen, OmniCom "locks up" on me (no cursor or response to keys). The same problem occurs when I'm in "more" and I type 'q' to quit. The most likely cause I can think of is that the emulator is not compatible with the "vt100" termcap/terminfo entry on this system. Can anyone who uses OmniCom with UNIX and vi, more, etc. help me out? (If nothing else, a termcap or terminfo entry to try, compare, etc. would help.) OmniCom is quite happy when I use it to log in to DELPHI (the screen even clears between Forum messages, at least in the Atari SIG where I spend my time).

Thanks in advance.

Re my last posting: I had mis-read the OMNIVIEW manual. It's the RAMDISK that is said not to work with DOSs that "hide themselves," like DOS XL in extended mode. I'll have to try it in UNextended (as-shipped) mode to see if at least that works. Since OmniCom (and OmniWriter also I hear) does not work with DOS XL, (and I don't like Atari DOS 2 much, and I have Percoms,) I am thinking about buying SpartaDos anyway. I am disappointed that the chip works with DOS XL but the programs do not - WHY? Another disappointment that I share with Fred Sullivan is that OmniCom does not map incoming characters properly for UNIX use, i.e. one sees the corresponding ATASCII graphics char's. instead of "{}~`". The doc. for OmniCom says that OMNIVIEW does something with these, and offers an update if needed, but my opinion is that the terminal software, not the chip, should do the translation. Why throw away Atari's characters for ALL applications? "No fair." (Besides, my OMNIVIEW isn't any older than my copy of OmniCom, really. What gives?)

Nick DiMasi ...!ihnp4!{ixlpt | ihlpm}!njd

P.S. I hope that CDY puts a key click into OmniCom in the near future. I never realized how much I depend on it, especially on a 130XE!

VT10^2 does work with a 130XE. I use it with an MPP-1000E
(Supra 300AT) modem. If you load Matt Ratcliff's (sp?) BASIC Switcher
to knock out BASIC (I hate using <OPTION>), then _Analog's_ Home-Made
Translator (or any other translator I guess) , and finally VT10^2
everything works fine.

I am interested in using OMNIVIEW (with OMNICOM) on my XE.
Does anyone know where I can get more info on it? This month's
Analog and _Antic_ don't seem to have any adds for the company that
makes it (CDY right?). Will it work with an MPP modem? Is it
possible to use the Fastchip without OMNIVIEW?

340. 256k upgrade and the future of the 8-bit

Newsgroup: comp.sys.atari.8bit
Date: 1987-03-31 16:03:18 UTC
From: jerrym@mmintl.UUCP
Message-ID: <2066@mmintl.UUCP>
Source record: 117744

I have seen on in the news here, talk of different memory upgrades but little or no mention of the RAMBO XL from ICD. I just installed it on my 800xl and it has given me 256k and 130xe compatibility as well. It is quite inexpensive and easy to install. I am currently running the 130xe version of the Paperclip word processor and have had no problems at all. It gives me a 112k text buffer to work with and in addition I can load the spell checker in memory as well.

Now my point,
this opens up a new arena for development for the 8-bits. With 4 times the memory, a lot of things are possible: mouse/window/gem environment, improved graphics capabilities (enhanced with the new 80 col card), "small monochrome" versions of ST software (highest color resolution on an ST is really graphics 8 on the 8bits) and the list could go on. This would make the 8bits true home computers that could do some real work and a lot cheaper than buying a IBM clone that costs more and have worse graphics and sound!

How does ATARI and the rest of you feel?

Jerry.....

341. ATR8000

Message-ID: <4UQ4Cuy00UhBlCI0u5@andrew.cmu.edu>
Source record: 117745

Does anyone own an ATR8000? I recently bought on for my Atari 800, and it is a great and wonderful thing, but I'd like technical information on it (schematics, port addresses, etc). (For those of you who don't know what and ATR is, it's a box that hooks up to the standard IO connectors, and contains a Z80 and (in some cases, mine specifically) an 8088. It lets you hook up 4 standard drives that you can buy from just about anywhere, including 8 inch, 5 1/4 DSDD, etc. It also has an rs232 port, a printer port, and acts as a print buffer. It works with any DOS, but best with MYDOS or SpartaDOS. It also lets you use the Atari as a terminal to the z80 running cp/m or the 8088 running ms-dos. whew....) Anyway, I have the standard SWP docs, but they don't go into much detail on hardware and low-level system stuff. Any help is appreciated.

Brett

342. OmniCom versus OmniTerm; ATR8000 info sources.

Newsgroup: comp.sys.atari.8bit
Date: 1987-04-03 16:15:32 UTC
From: jhs@MITRE-BEDFORD.ARPA.UUCP
Message-ID: <8704031615.AA25686@mitre-bedford.ARPA>
Source record: 117746

Nick DiMasi said of CDY's OmniCom "Some call it OmniTerm". Actually, OnmiTerm is a different program, which was contributed by an OMNIVIEW owner in Canada and distributed free of charge by CDY. It uses the OMNIVIEW 80-column screen capability effectively, and also provides upload/download capability, which VT10SQ does not have. OmniTerm is a "vanilla" terminal emulator and not a VT100 emulator like OmniCom. Also, OmniCom supports the kermit file transfer protocol and OmniTerm does not.

I used OmniTerm quite a bit before CDY came out with OmniCom, but since I need the VT100 features for the screen editor I normally use, I prefer OmniCom these days.

Brett Kuehner wanted information on the ATR8000. If you don't get all the information you need elsewhere, try my favorite Atari hardware/software guru, Paul Swanson, of NiteLite Systems, Billerica, MA. His phone numbers are: (617) 663-4221 (BBS) and 663-4463 (voice). If possible, use the BBS as Paul prefers not to be interrupted with voice calls unless absolutely necessary. (Paul is an Atari sales/service dealer and designer of proprietary hardware and software. He is an excellent source of help with tricky problems, including repairing things that others have given up on. He is thoroughly familiar with the ATR8000.)

LOWEST resolution on the ST is equivalent to the 8 bit's graphics 8.
That's why the 8 bit can only display 40 columns legibly (low res on the ST
is 40 columns). I do agree that 80 columns on the 8 bit would make it a
worthy entry in competition with other home computer word processing/accounting
type machines.

Work is underway to transfer the program library from Score.Stanford.edu
to a bitnet host which will make it available using LISTSERV. This will
permit everyone to request programs from the library just by sending e-mail.
At present we are waiting for a tape to move the existing files.

However, we are willing to accept new contributions. Contributions will
be reviewed. The standards are evolving, but in general all programs
should be accompanied by .DOC files. The moderator is Arnold de Leon.
His address (from Arpanet -- others please translate) is

There is (was?) a company called Zobian Controls that sold a mouse (they call it a Rat) and an operating system to take advantage of it called RAOS. I have just recently gotten interested in trying to incorporate a mouse for several applications and have tried calling their phone number but do not get an answer. I don't know if they take advantage of extra memory upgrades but it shouldn't be too hard to do. Anyone know if they are still in business? Has anyone tried or currently use their mouse and operating system?

347. OmniCom, UNIX, and vi

Newsgroup: comp.sys.atari.8bit
Date: 1987-04-07 04:11:13 UTC
From: njd@ihlpm.UUCP
Message-ID: <1052@ihlpm.ATT.COM>
Source record: 117751

In a previous posting, I reported that I was not able to get OmniCom to work properly with vi on this system (ihlpm, an Amdahl UTS system). I since was able to log in to uniqvax at my home office (I am a contractor), a VAX running System V Release 3 (my company ported it) and OmniCom and vi got along fine! Also, I tried a lab support VAX here at Bell Labs and vi worked with OmniCom there. Finally I noticed that whenever a line longer than the screen was output, not in vi, but just when at the "shell level", OmniCom would not wrap it. Instead, the characters just "buzzed" at the end of the 80-column line. I looked over my notes on a hard copy of the dec.ti (terminfo source for DEC terminals) file and realized that what I had was not a "vt100", but a "vt100-nam" according to dec.ti. I tried TERM=vt100-nam, and that caused vi, more, and vnews to work just fine (on this UTS system and another here).

So, I can now join my voice to John Sangster's and others in recommending OMNIVIEW and OmniCom to anyone who wants to use their 8-bit Atari as an 80-column terminal. I am writing this article on it right now, and it is working fine. It does insert and delete line, but no insert/delete character (but "redraw" is tolerable-to-fine at 1200 bps, at least for me). OMNIVIEW and OmniCom were well worth the wait. Now, Mr. Young, about that "ascii capture" and "lostkeyclick (the latter I am beginning to get used to, actually)...

Nick (happily 80-column-ing at last) DiMasi

P.S. Oops, sorry I confused OmniCom and OmniTerm... they really are different (but I haven't tried O'Term so I can't comment on it).

350. New Version of OmniCom from CDY

Newsgroup: comp.sys.atari.8bit
Date: 1987-04-08 00:50:57 UTC
From: jhs@MITRE-BEDFORD.ARPA.UUCP
Message-ID: <8704080051.AA26509@mitre-bedford.ARPA>
Source record: 117754

In response to a question by Nick DiMasi which arrived without a return address (and I am often too hasty about deleting earlier messages which might have the return address), yes, CDY *HAS* added ASCII data capture to the latest version of OmniCom, and not only that, but also a very handy "Print Screen" function. The ASCII capture can go to the printer if you have more than a single screenful of data to capture, but for many applications like printing short e-mail messages, the single screen capture mode is more convenient. For one thing, you can decide after the data arrives that you want to print it. Also, all you have to do to print what is on the screen is turn on your printer and press SELECT and OPTION simultaneously.

For those who aren't familiar with it, OmniCom is a vt100 emulator program available as an accessory to CDY's OMNIVIEW 80-column upgrade chip for the 800/XL/XE computers. I believe it to be the most complete vt100 emulation available and it also supports kermit and xmodem for error-free file transfers. With the addition of ASCII data capture and "Print Screen" functions, it is probably the best terminal emulation program around for the 8-bit Ataris, and certainly the best vt100 emulator I have seen.

CDY's mailing address is: CDY Consulting, Inc., 421 Hanbee, Richardson TX 75080. Their phone number is (214) 235-2146. I have no financial interest in CDY Consulting, nor, alas, in most other profit-making companies.

There is (was) a company called Zobian Controls in PA that advertized in ANTIC that had a mouse called the SuperRat and an operating system called RAOS (Rat Actuated Operating System) that gives you windowing and icons just like the ST. I would like to have one of these to play with. Does anyone have one or know if the company is still in business? They do not answer their phone (and their ad is not in the May issue of ANTIC). I have written to them but I will not send a check until I can actually talk to someone and confirm that I will receive something in return.

354. HELP! 256K memory upgrade

Newsgroup: comp.sys.atari.8bit
Date: 1987-04-09 12:54:31 UTC
From: store2@ihuxi.UUCP
Message-ID: <1582@ihuxi.ATT.COM>
Source record: 117608

HELP!!!
I have a 600XL that I modified with a 256K memory upgrade that was compatible with the memory upgrade published in BYTE. I have now decided to modify the circuit to make the memory upgrade compatible with the 130XE. I have modified my circuit based on information published in Antic (Feb. 1987) on how the bank switching of memory works in the 130XE. My modification appears to work fine with the software published in this issue of Antic, but does not work with the ramdisk driver in Sparta Dos. The following are the definitions of the bits in PORTB and signals used by my circuit.

PORTB Bits
PB2 & PB3 - determine which 16K bank of 4 is used in extended memory mode
PB4 - extend memory mode bit for CPU (when low CPU is in extended memory mode)
PB5 - extend memory mode bit for ANTIC (when low ANTIC is in extended memory mode)
PB6 - unused
PB0 & PB1 & PB7 - used to bank switch between ram and basic/os/fp rom

Signals used
HALT - when low ANTIC accesses memory, when high CPU accesses memory
MUX - this is the select lead between the ras address (when low) and the cas address (when high)
A15 & A14 & - address bits used (a0 & a7 are for the ras address, A0 & A7 a15 & a14 are for cas address and decoding bank switched area in memory)

My questions are:

Does anybody see a missing registered bit or signal that needs to be added to this list?

Is there a better source of information on the details of using the memory bank switching capabilities of the 130XE?

What other registered bits do the other 256K 130XE compatible upgrades use to get to the additional 128K of memory?

356. A-Rogue

Newsgroup: comp.sys.atari.8bit
Date: 1987-04-09 14:49:03 UTC
From: ssegan@dasys1.UUCP
Message-ID: <320@dasys1.UUCP>
Source record: 117610

Okay now. I've had A-Rogue for about a week, having bought the disk at
B. Dalton out of anxiety. This is what -I- think of it.
The BASIC program is 125 sectors, which leaves mucho room for improvement.
And the game could use some.
The character set is a nine sector file and is beautiful. Graphics 0, by the
way.
Now to the program.
A board is small, a bit less than one screen, made smaller by the fact that one
space is a 2x2 to 3x3 character block. There are twenty-eight monsters,
varying only in three attributes: AC, HP, and level they are found on.
You can't see a monster coming. When you step into its square, it attacks
you --- but such a routine would be very hard on such a small level.
(How far can you run?:-)) There are three spells, Heal, Teleport, and
Fireball, and each is instantly identified when you pick it up. There
are also seven potions, which in typical Rogue fashion you must DRINK to
find out whether you'll die or not.:-) The game is fast enough, as it's
mainly strategy.
You have to get to the tenth level and find the Jewel of Taldra. You don't
have to get back up --- the Jewel teleports you home.
And finally, there are no rooms in the typical Rogue sense. There ARE
chambers, however, where passages meet to form a small cavern.
BUT, it's overall a good game, considering the size and language. I'm thinking
of modifying it to make it bigger and better.

I've said my piece.
----Sascha!

357. 256K and 80-column upgrades and little mouses...

Newsgroup: comp.sys.atari.8bit
Date: 1987-04-09 20:26:38 UTC
From: jhs@MITRE-BEDFORD.ARPA.UUCP
Message-ID: <8704092026.AA26563@mitre-bedford.ARPA>
Source record: 117611

A word about 256K upgrades and 130XE compatibility:

Jerry Martinez reports using the RAMBO-XL with Paper Clip and says that this shows "130XE Compatibility". Actually, the Newell 256KXL board would run this software just fine as well. The incompatibility only shows up when you try to run graphics-oriented software like Xlent Software's "Typesetter" program, which puts ANTIC (the graphics processor in the 8-bitters) up on the new banks of memory. I am not familiar with exactly how a RAMBO board works, but I have been told that it has the same problem the Newell board does with ANTIC modes. The problem arises from a fundamental problem: At first glance there do not seem to be enough bits in the byte at $D301 to select all the banks and still leave Bit 5 free to switch the ANTIC mode, as a 130XE does. Unless ICD came up with a scheme like the one I used in my modification of the Newell board, they also would not have enough bits to work with. Probably the RAMBO board could be modified in a similar way, I don't know. However, the Newell board with my modification is the best that can be done to keep exact 130XE compatibility but still add the extra memory -- I think this is a "mathematically provable" claim. I have also heard that the RAMBO board does not have the "memory protection logic" of the Newell board so is less forgiving of programming errors: it may trash your program by overwriting non-banked memory. The Newell board protects against this, as does my modified version of it.

Re: 80-columns NOW!!!

Dean Brunette says "LOWEST resolution on the ST is equivalent to the 8 bit's graphics 8. That's why the 8 bit can only display 40 columns legibly..."

Actually, you can get a very legible 80-column display RIGHT NOW, for $39.95 from CDY Consulting, and it is the OMNIVIEW upgrade that some of us have talked about. I know it is PATENTLY OBVIOUS that this is IMPOSSIBLE, just as it has been shown that bumblebees can't fly, but all I can say is I have been using OMNIVIEW with a Magnavox amber monitor for most of a year now, and it is just about as satisfactory as using my "real" vt100 at work, though admittedly the resolution is a bit lower. But it is good enough that you quickly forget that it CAN'T POSSIBLY look that good and start enjoying the convenience of true 80 columns and full-screen editing. I even used OMNIVIEW's 80-column mode with a monochrome TV set (an old Sylvania nearly 20 years old), and it worked quite well.

Personally, I think David Young has cheated somehow and slipped in some extra pixels that he isn't talking about, inside that OMNIVIEW chip, or maybe it's a bunch of elves, but however he did it, it works amazingly well.

Re: little mousies for the 8-bitters and interfacing nonstandard disk drives. If you want to do these things NOW, you might contact Paul Swanson, of

NiteLite Systems, Billerica, MA. His phone numbers are: (617) 663-4221 (BBS) and 663-4463 (voice). If possible, use the BBS as Paul prefers not to be interrupted with voice calls unless absolutely necessary. Paul can help you with custom interfaces (e.g. 3.5 inch drives, IBM-PC compatible drives, etc.) and has a nifty little mouse gadget that I won't say any more about but maybe Paul will sell you one if it's into production yet. And if it's not, and you want to become a venture capitalist...

358. Gemini 10X printer (Star Micronics)

Newsgroup: comp.sys.atari.8bit
Date: 1987-04-10 04:45:13 UTC
From: gail@alberta.UUCP
Message-ID: <1115@cavell.UUCP>
Source record: 117612
Cross-posted to: comp.misc,comp.periphs,comp.sys.apple,comp.sys.atari.8bit,comp.sys.cbm

I posted news a while ago about a problem that I am having with
the Gemini 10X printer. The problem was a print head jamb to the
left on the odd carriage return. Because I did a little
research and I did get a couple of replies, I will share the scoop.

Star Micronics has good customer support. I have written a few times
and always get prompt replies. I wrote asking if there has been a
bug discovered with there Gemini 10X printer like the one I described.
It turns out that they will send you the newest version of EPROMs free
of charge. Just send in your old ones when you get the new.
But before you all rush out and ask for new ROMs you may already have the
newest version. Open up your Gemini by taking out the two screws on top
at the back. The circuit board is back there and has a CONTROL version
stamped on it near the front edge. If you have control version A, then
the newest EPROMs are GX1.4. There is a pair of EPROMs, but they should
both say 1.4 on them somewhere. If you have control version A and don't
have 1.4's then write and get new ones. The address is in your manual.

If you don't have control version A, then write to see if you have the
newest version of ROMs. Some of the bug fixes in control A are:
super/sub scripts, lower case 'j' descender, ribbon jamb with block
graphics.

I'd like to thank John Linzy at Star Micronics for such friendly service.

Scott McPhee

Thanks for the reply, at least now I know my articles get out! :-)

I guess my line should have read, "...can only display 40 columns legibly
IN MY OPINION..." I can't stand Omniview, and prefer the crispness of the
Atari XEP80 (which is fantastic!) or an ST or an IBM (at even 640x200).
Maybe it's just that I don't like my lower case N's to look like this bit
map:

```
N
N N
NNN
N N
N
```

I'm sorry; I prefer using my Ampex 220 terminal to the Omniview (even
though it has a bit higher resolution, i.e. four times as many pixels).

Actually, while they took out several full-page color ads for the mouse and RAOS, to the best of my information there were none ever shipped. In fact, Zobian had pre-paid for a booth at the Allentown Atari Expo, not far from his home, and was a no-show. I doubt this product is ever going to happen.

On the other hand, if something like this were developed, Atari Corporation would be seriously interested in helping.

Not only is there a keyboard expansion, but the keyboard is *included* when
you buy the unit. This is ostensibly to provide a controller for more
sophisticated games that need the keyboard, like Flight Simulator (which
will be one of the three pieces of software bundled with the system).

You also get 64K of RAM, the standard XL/XE OS and BASIC in ROM, and an SIO
port.

Isn't marketing interesting? Mass merchants who won't touch 8-bit computers
with a 10-foot pole are dying to get their hands on this XE game system.

While Omnicom is a better program, I've seen quite enough praise for it. I've been using VT-10^2 for some time now and I'd like to say try before you buy as vt10^2 works pretty well as a VT100 emulator for my uses.

Before you ask, I have 7 computers, and thus anything that's plugged in is a canidate for calling to my Sun at work. As it happens, the most available machine in the house is my 800 XL (in an 80 column mode.) There are several phone lines, so it being close, and having _both_ a 1030 and an 850 interface (which competes for a 1200) I have all sorts of neat terminal progam choices.

So far, that choice has been vt10^2. It's not perfect as an emulator (and that's being generous) in that it doesn't support line deletes and a couple other things, but for the bulk of vt100 work, including using vi to edit this message, it works just fine. Being available free on many BBSes (my Detroit node included) doesn't hurt, nor does the IBM PROFs emulation. (Though I never have occasion to use it, we did just get a 3090.)

In fact, given the source code to vt10^2 I'd love the chance to add features and complete the emulation. I like the fact that it works with either the 850 or the 1030, but it doesn't work with SpartaDOS which is a moral sin. Just remember : SpartaDOS = good, anything else = evil. If anyone has the source to it, send it my way.

This has NOTHING to do with CDY. I certainly want Dave to do business (hell OMNIMON should be in EVERY Atari!) but there's no reason that Atari's, with their LONG history (at this point) of technically oriented programmers, can't have the fine public domain software that you see on IBM's. Some of it is there - Express, Speedscript, DVC/65 C compiler, so lets help it along.

PD to a fault,

You should have said "in my MISGUIDED SNOOTY opinion". Lower case N's
don't look anything like your representation. I suggest you become
better informed about a subject before expressing such strong opinions
in a public forum. The other comparisons you make are ludicrous. How
are the ST, IBM, or Ampex 220 terminal going to help you get 80 columns
on your 8 bit Atari? Only the XEP80 falls correctly into that category
and it is not even available. The OMNIVIEW on the other hand has been
available for years and has thousands of satisfied users.

David Young

P.S. Do you think Atari is really serious about supporting the XEP80? I
was promised by Richard Frick (I hope that is spelled correctly) of
Atari before Christmas that I would be shipped a prototype XEP80 within
2 weeks so that I could see about converting my 80 column software to
it. Have not heard from them since.

hello, guys,
I think I may have posted this already, but ...

As of the end of this week, I am leaving the net indefinitely.
I am moving from Cleveland, Ohio to Columbus, Ohio to find a REAL job.
I have really enjoyed meeting many of you, this is a one-of-a-kind forum
for serious 8bit owners, and I think that the future is still very bright
for the 8bits particularly thanks to ICD of Chicago and their excellent
products. Look for new tools like roff and a new REAL C compiler to come
out in the near future.

If any of you would like to contact me, send USnail to my present
address, and hopefully it will get forwarded:

I guess all Californians are snooty, eh Dave? I've had an Omniview for about 3 years now, I think I've used it enough to realize I don't really like it. Call it snooty if you will. I can't see how you can blast someone from giving an honest opinion.

And although it's not a supported product, I might add it is quite simple to use a terminal on an 8 bit... use SpartaDOS (an excellent product, and the 80 columns on their MIO board looks quite nice, I might add it is worth waiting for) to redirect to and from the serial port. It's really not effective (costwise and usage) but it isn't as difficult as you point it out to be.

Lastly, Atari lent me an XEP80 to use for display at the West Coast Computer Faire. A nice unit also, and AtariWriter+ for it makes it an easy transition from 40 columns to 80. It also has a standard printer port (ala ST, IBM, etc.) on the back so if you need an interface at least you won't have to hunt down a funky cable. It may be vaporware, but I feel it's worth waiting for as it's a product which will breathe new life into MY 8 bit.

(By the way, I DID go out and get a monochrome monitor to use it with. You want praise? OK, you did a good job making a 4x8 character set. But 4x8 just is not acceptable to me. 'Nuff said.)

> N

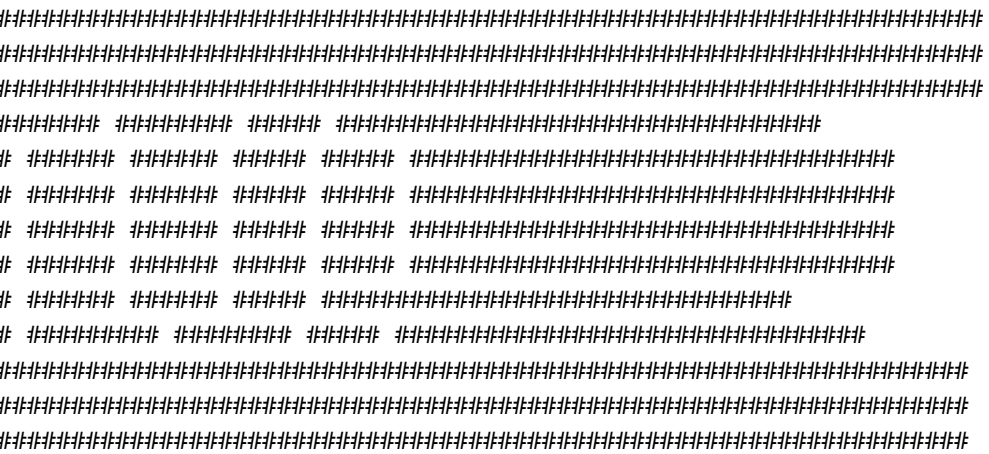
I was going to reply to this comment earlier, but David Young beat me to the punch. (Darn near literally, at that!) However, he did not get specific: The lowercase n in OMNIVIEW's character set is represented more like the n in the following:



I have tried to make the rendition look accurately like the OMNIVIEW rendition, and I must say the exercise has reinforced my feeling that David Young "stole" some pixels from somewhere. I simply COULD NOT make it look right on a smaller scale. Partly this is because I didn't have solid scan lines to work with. Anyway, the rendition looks quite accurate on my printer, except that in this magnification, the characters look uglier and more "quantized" than the actual OMNIVIEW font on my monitor. Try looking at ANY dot matrix font under a magnifying glass and you will see the same effect. Anyway, the bottom line is, to see what it really looks like, you should stand back from the screen or printout about as far as possible so that the # signs blend into a continuous background and the letters blend into continuous shapes. If you do this, you will see that the "n" really looks like an "n", and bears little resemblance to Mr. Brunette's rendition of it. I can't imagine where his version of an OMNIVIEW "n" came from, perhaps he has a

defective version of OMNIVIEW or something. All I can say is, if your reproduction of the above "now" looks anything like the one I printed on my printer (using OmniCom's nifty new "Print Screen" function, by the way), then you have a FAIRLY ACCURATE rendition of what it would look like with OMNIVIEW on a good monochrome monitor. Except be SURE to stand back far enough to lose the dot matrix effect when you look at it. And I would also say that the image on my monitor of the actual word "now" looks a bit better than the fake version on the printer. Somehow the "n" has a more rounded shape at the top! (Yes, I *KNOW* that this is IMPOSSIBLE!)

I reiterate that OMNIVIEW looks best in dark letters on light background. It appears to me that in this mode, the eye "fools" the brain into seeing the letters as having a rounded shape, seen in silhouette against the bright scan lines of the raster. The brain fills in the rounded segments with more or less complete freedom where the dark silhoutted character passes over a dark interval between bright scan lines. Naturally, the brain computes some magnificently smooth interpolating function where it is free to put the data anywhere it likes (black character passing over black area between scan lines). The end result is a character set that is just plain BETTER LOOKING than it has any right to be!!! If you switch to light characters against a black bacground, then the characters are dotted to begin with because of the dark areas between raster lines, and the brain now HAS TO see just what is there -- the dark stripes hurt rather than helping. You will have to see a real OMNIVIEW font on a real TV or monitor to fully appreciate the above.

OMNIVIEW definitely is a compromise approach, as even David Young would I am sure be the FIRST to agree that more than a 4x8 dot matrix would be far better for creating a "pretty" font. However, David has definitely shown, in my opinion, that a USEABLE font can be constructed in 4x8 format. Since OMNIVIEW is currently available, and comes WITH A WORD PROCESSOR at $39.95 list, and it also gives you a built-in RAMdisk handler and ends the Translator Disk Hassle, I still stand behind my recommendation of it as a reasonable approach to getting 80 columns on your 8-bitter. With the trend to 16-bit machines moving right along, $39.95 sounds to me like a lot more reasonable figure to invest in upgrading an 8-bitter than $80 or so.

Of course if you need a printer interface more than a free 80-column word processor, one of the other products might be a good way to go. Especially if you don't need it for a few (?) months and if you are especially critical of screen fonts and if you plan to keep your 8-bitter forever and WANT to pay for the best resolution you can (someday) get. Ya pays yer money and ya takes yer choice!

I have vt10sq and it works fine under SpartaDOS. It even works with a
custom RS232 handler (I use the R-VERTER interface), and doesn't require the
translator disk for my 800XL. Yes, I would also love to see it with
complete vt100 emulation, especially line deletes. Unfortunately, I do not
have the source.

Dark letters on a light background may look better to you, John, but I don't agree that the display is ALWAYS better that way. In fact, in my case, I tend to go "blind" and/or get a headache when looking at an inverse video display like that. I have my copies of OmniTerm and OmniWriter set up to display light characters on a dark green background (how dark depends on the brightness setting on the monitor). Also, OMNIVIEW from DOS or BASIC is easier for me to read after I use the <SELECT>, <some-char> background-color toggle to switch to light-on-dark.

You may have something there about the brain perceiving the characters as being more rounded than they are, even more so in the dark-on-light mode. I just can't use the latter.

BTW, have you had any trouble changing the text color in OmniCom? I was able to play with the background color, but the text insists on being white (tho last time it was light green).

> problem occurs when I'm in "more" and I type 'q' to quit.

I use OmniCom on an model 800 dinosaur, so I don't know if the following is relevant. I don't have a problem with lockup at the beginning of vi, or after 'q' in more, but I do experience (infrequently) a lockup if the machine sits for a few minutes, or sometimes (seemingly) at random. I discovered that when this happens, doing option - b unlocks things, and everything is back to normal. This is somewhat comforting. Option - b is supposed to send a break, but doesn't send anything which is recognized as a break by either Unix or our resident IBM main-pig. I guess it's only reasonable that it be good for something.

Since your problem occurs when using vi, it may be that the vs and ve entries are doing it. vs is "visual start" (send by vi to initialize) and ve is "visual end". My termcap entries for vt100 don't use these, but maybe yours do. It seems strange that more would send something like this, though. I suggest that you look at the termcap to find these, and experiment if they're defined. You may be able to put in a new termcap entry without whatever the offending string is.

One comment on termcaps -- the only problem I've had is using GNU-Emacs at 2400 baud. When scrolling up, OmniCom just can't keep up. For those who aren't in the GNU, Richard Stallman thinks that x-on x-off is a stupid method of flow control and refuses to use it. If I ever do anything half as impressive as GNU-Emacs, I'll feel qualified to take issue with this viewpoint. In fact, ctrl-s is the key binding for a search. Since I really didn't want to change that key binding, I had to fix things so the old 800 could keep up. I did this by putting reverse-scroll delay in the termcap.

A comment about monitor hookups. It is crucial that the monitor output be hooked to the luminance pin and not the composite pin. This causes some problems with other programs -- you can't distinguish colors at all any more (colors show up as patterns on a green screen with monitor output hooked to composite), but it makes Omniview usable. (The display is terrible otherwise).

Despite any problems or complaints that I have, I still think that Omni... was well worth the $49.95 (yes, dinosaurs are more expensive) I paid for it.

A few comments: I think that color is a *really* *important* factor in how good people think that Omniview looks. I went into a store in MA looking for an Omniview demo: the people said that they did not have any in stock but they would show me a demo and then see if I still wanted it. They did show me a demo and indeed it looked *really* *terrible*. To the point of illegible. I was bummed and went home wondering how anyone (like jhs) could possible praise this thing.

Then I got ahold of VT10**2 and tried it at home. Essentially the same results. Characters running into each other, rainbows, blurry uck, etc. Finally I tried a different version of VT10**2 (I'm a glutton for punishment) and VOILA! I could not believe how good it looked. At first I had to count the characters to really believe that I had 80 columns. Just for the heck of it, I unplugged my monitor and hooked it up to a regular old color TV. Still not bad! (BTW I have an 800XL and a Commodore 1702 monitor).

Anyway, I started looking at the differences, and noticed that the good looking one was running black characters on a white background. The ukky one was light (white? I don't remember) on black. I don't remember what the Omniview demo colors were, but it was not black on white.

Anyway, my theory is that if you choose the wrong colors, you get all sorts of artifacting causing color stripes across the characters. These stripes then screw up your eye's edge-detection algorithm. My continuing theory is that Omniview is probably as good as VT10**2 (in looks, that is), but I just have not seen it with the right colors. JHS uses an amber monochrome monitor, so he is immune from these problems.

Perhaps David Young or someone can comment on bad and good color combinations?
I'd be interested in knowing how rare good combinations are.

Nick DiMasi comments:
> ...I tend to go "blind" and/or get a headache when looking at an inverse
> video display like that. I have my copies of OmniTerm and OmniWriter set up
> to display light characters on a dark green background...

This is of course a matter of personal preference, and I can see how you would be less satisfied with OMNIVIEW's font than I am if you start with the firm constraint that you MUST use light letters on a dark background. However, I have heard it alleged that amber monitors produce less eye fatigue than other colors, and that green is especially bad for eyestrain. It may be that you would find dark on light less objectionable on an amber monitor. Even a TV-like white screen might be better than green. I have used both of these colors with OMNIVIEW but I have not tried a green screen. I would certainly recommend that anyone planning to do word processing select an amber rather than a green monitor, independently of choices like whether to use OMNIVIEW.

> BTW, have you had any trouble changing the text color in OmniCom?
> I was able to play with the background color, but the text insists on
> being white (tho last time it was light green).

As I said above, I have used a monochrome TV and an amber monitor, but never a color monitor on my Atari, so I have never observed color effects. I have, however, had no trouble changing the brightness of text or background in OmniCom. By the way, I have never yet seen a color monitor that didn't make text look fuzzy, except for the NEC MultiSync, which I find just barely sharp enough. Anyone comparing OMNIVIEW with the Atari or ICD 80-column display adaptors should be careful to do so on the same monitor they will actually use them on!!! Seeing them on different monitors could make a BIG difference.

Joel Plutchak writes:

> ...Koronis Rift ...runs on all kinds of "impossibly slow"
> machines (I have in mind particularly the 6502-based Atari 800 series).

This brings to mind the report some time ago of the "bouncing ball" demo running side-by-side on an Amiga, an ST, and a 130XE. The reporter said that the animation was BY FAR the best on the 130XE. Don't underestimate the power of that little ANTIC chip in the 8-bitters!!! Also, for passing bytes around and controlling things in realtime, don't OVERestimate the advantage of an 8-MHz 68000 over a 1.8-Mhz 6502!!! Many factors are involved in bottom-line performance, and the more than 4 to 1 higher clock speed is ONE of them. Another is the fact that the quickest 6502 instructions take 2 clock cycles, while the 68000's quickest instructions, if I read the book arightly, take 14 or so. (Well maybe 8 in a few cases?) That's SEVEN to one the OTHER WAY, i.e. the 6502 is AHEAD at the moment by nearly TWO TO ONE! Then again, the more flexible addressing modes of the 68000 may require many fewer instructions to do the same thing. For most tasks, the 68000 is probably 3 or 4 times as fast as the 6502. Probably there are tasks where the advantage is greater. And probably there are a small set of tasks where the 6502 can equal or SLIGHTLY EXCEED the speed of the 68000, which it would definitely do if it could use almost exclusively 2-clock-cycle instructions and about the same number of them per loop as the 68000! Then, of course, there are the ANTIC and the POKEY to consider, and if you are talking animated games, they count for A LOT!!! With all of these facts in mind, it is not at all surprising that the 8-bitters can hold their own with the newer 16-bit machines in the limited arena of games.

Long live the 8-bitters!!!! LOAD and STORE forever!!! (Which is what it SEEMS like when your are programming them!!!)

Has anyone out there managed to get the ARCX that's been posted several times to run on a vanilla 800-XL? I've hauled it down, decoded it, and tried to run it a number of times, without success. I've tried it under DOS and DOS XL. I poked around at it with my debugger, and it looks like it's dying while calling off into high memory (the OS rom) at init time. I currently suspect that it was written for an 800, and the entry points have moved on an XL. Apparently it works under Omniview; but that makes the OS act like the old 800 one. I'm out of ideas. Anybody got any info? Or the sources?

381. Farewell

Source record: 117635

Farewell to Brad Banko, whose participation I will miss. I hope he finds a path back to us in the near future. Meanwhile, I have a comment to make on his farewell message.

He writes...

> I have really enjoyed meeting many of you, this is a one-of-a-kind forum
> for serious 8bit owners, and I think that the future is still very bright
> for the 8bits particularly thanks to ICD of Chicago and their excellent
> products. Look for new tools like roff and a new REAL C compiler to come
> out in the near future.

Actually, The PRINT TOOL is an implementation of RUNOFF for the Atari which is ALREADY available. I'm not exactly sure how ROFF and RUNOFF differ, but they are at least different generations of the same idea. This excellent program makes it possible to turn out completely professional-looking reports and book manuscripts, not to mention Vu-graph slides, on your 8-bit Atari. The program is extremely well documented, in my opinion. The manual, which as I recall is some 70 pages long, is itself an example of the professional quality of document that can be produced by The PRINT TOOL. It includes features such as automatic decimal numbering of sections (if you want decimal numbering), and it produces the Table of Contents automatically. Not only that, but if you take the trouble to flag all the items you want mentioned in the Index, it will construct the Index for you also. This product is an unusually good software value at the list price of $20 and has been on sale recently for about $15. You can buy it through ANTIC or directly from the vendor. To order, check your ANTIC catalog or write to:

Computer Educators Inc.
2906 Covington Road
Silver Spring, MD 20910.

You use The PRINT TOOL with any word processor that produces standard ASCII files, such as AtariWriter, Paper Clip, SpeedScript, or OmniWriter (CDY's 80-column WP program). You insert formatting commands as described in the manual, and The PRINT TOOL does the rest.

I am not in any way affiliated with Computer Educators, Inc.

Message-ID: <8704241712.AA00959@mitre-bedford.ARPA>
Source record: 117636

Does anybody know if there is a version of arc/arcx around which works correctly on the modern 8-bitters (XL/XE)? John Dunning reports that the version I sent him does NOT. It does however work fine on his 800 and on my 800XL with OMNIVIEW. Others would probably have to run the Translator Disk. That sounds rather silly, so I would like to get a more compatible version.

Source record: 117637

I don't have a copy of the compiler for the 800 but only for the XL/XE.
Does anyone else on the net have any info on an 800 version?

I don't know anything about the copyright on any of this software. It was
claimed to be Public Domain, but there is a copyright notice saying the
program belongs to "Happy Computers". I have heard nothing about this from
anywhere but the title screen. Has anyone heard anything to conflict with the
Public Domain status of Turbo BASIC?

-John Sangster / jhs@mitre-bedford.arpa

384. Ace C status and info

Newsgroup: comp.sys.atari.8bit
Date: 1987-04-26 18:29:00 UTC
From: SULLIVAN@suny-bing.CSNET.UUCP
Message-ID: <8704280110.AA05415@ucbvax.Berkeley.EDU>
Source record: 117638

Some time ago there were requests for Ace C. I wrote to the author (Ralph Walden) about the status of Ace C. I will paraphrase his reply.

Deep Blue C was written by Jack Palevich and distributed by APX. When APX died, J. P. gave Ralph Walden permission to place into the public domain an improved version. This version is Ace C. R. W. made further improvements, and released DVC/65 (not in the public domain!) In the meantime Antic bought the APX inventory and started distributing Deep Blue C again. "Due to heavy piracy" (R. W.'s words) R. W. was not able to make any money from DVC/65 and sold the rights to Clearstar Technology. They are now selling it as Lightspeed C. (More about that in a moment). Again quoting R. W. : "Obviously neither Jack Palevich or myself are very happy about ACE C being out there. I am in the unusual situation of having to compete against myself having written both Lightspeed C and ACE C. However, ACE C is in the public domain and you may distribute it as you see fit."

I am posting ACE C (an accompanying message) but, I'll include the following ad for Lightspeed C. L. C. comes with an editor/compiler/linker/executor which, like Turbo Pascal, puts you back into the editor looking at your syntax error if one is found. It is claimed that L. C. will compile and link the sieve example (which I included) in under 5 seconds with a ram-disk. It is available for $39.95 from:

Clearstar Softechnologies
1501 Wood Ave. #36
Sumner, WA 98390
(Usual disclaimer + this info is from a Clearstar ad - I do not own a copy of L. C.)

Note -- None of these compilers compile into native code. They all compile into an intermediate code, (analogous to P-code) and this code gets interpreted at runtime. Also, they do not have such esoteric C constructions as:

structures, unions
multidimensional arrays
float, double
macros with parameters

A few days ago Brad Banko mentioned a forthcoming "real" C compiler. Does anyone have more information? Frankly I'm tired of not having a decent programming language for my machine, and I would welcome such a compiler. (No, I don't regard Basic as a decent language - but I don't have the energy to debate, so please don't flame at me.)

I haven't made too much use of Ace C, but I haven't seen problems other than the lack of language features and the strange syntax -- $(and $) are used for braces since { and } don't exist on the Atari keyboard.

I uuencoded the binaries using Ultrix uuencode. I hope everything is ok.

388. Review of Great Lakes Atari Expo at Buffalo

Newsgroup: comp.sys.atari.8bit
Date: 1987-04-27 05:19:49 UTC
From: bruce@ektools.UUCP
Message-ID: <643@ektools.UUCP>
Source record: 117642
Cross-posted to: comp.sys.atari.st,comp.sys.atari.8bit

Following is a review I wrote for the ACORN KERNAL, our user group newsletter, about the Great lakes Atari Expo held this weekend in Buffalo.

--

It wasn't the CES, or COMDEX, or even the Allentown Atarifest, but it was the first major Atari show to be held in western New York State. The Great Lakes Atari Expo at Buffalo was held April 25-26 at the Buffalo Convention center.

After my kids collected the requisite balloons, etc. and talked with COSMO, the Robot, at the entrance, the largest thing I saw was the Atari tent I've heard about. And the first thing I saw in the tent was the long awaited Atari Laser Printer hooked to a 1040ST. Art Morgan of Atari was demonstrating it using 1st Word. He said that it will work on a 520ST in Diablo 630 emulation mode, and on a 2 meg Mega-ST for full bit-image graphics. It will cost as previously announced, and will be available this Summer (although I heard as early as May from other people). According to Neil Harris, this was the first public showing of the laser printer in its final configuration.

Landon Dyer from Atari was showing two 1040 ST's, one with a blitter chip, and one without, both showing the flying bird demo. I thought the demo was really nice without the blitter. But with the blitter, the demo was smoother and noticeably faster. Landon said that the blitter will also be available this Summer in the Mega-ST's and in the late Fall for retro-fitting to current ST's.

He also said there will be some, but not all bug fixes in the blitter roms. The underscore bug is fixed in ROM, but the 40-folder problem is not in ROM. It is fixed by a (pick one: officially to be released, unofficially already released) patch called FOLDRXXX.PRG.

One interesting thing were the PS3000 color monitors with the built-in disk drives which were being used by the Atari people. Evidently, they started to be produced, but never made it to market. I heard more than one visitor ask where they could be bought.

Also being displayed was the XEP80 adaptor for the 8-bit line. It plugs into the joystick port and provides full 80 column text

in black and white on a color or black and white monitor. A driver program is loaded from an AUTOEXEC file to enable the device or without the 80 column mode being enabled.

Easily the loudest and best sounding booth was Bob Collister's Wind Chimes Music midi demo. Bob's Bose speakers were pumping out some of the best computer generated music ever heard. And for those people who wanted to remember the experience, he was selling cassettes of some of his works, including the ACORN ST theme.

Nearby was a long table full of ST's where lines of people were waiting to play Xanth's Midi Maze game, where several ST's are connected via the Midi bus to interactively search out the other players.

Microware Distributing from Albany, who are Atari's official distributers (that means they're the guys our dealers buy from) for our area had an assortment of various synthesizers on display and were marketing the musical capabilities of ST systems.

Royal Software of Eugene, Oregon was introducing their new war strategy game, Great Battles 1789-1865. They were also showing their other programs such as EZ Calc, EZ Data, and Payroll Master.

John DeMar, Bob Dolan, and Clint Parker were at the QMI booth showing the finished versions of DeskCart, the multi-function desk accessory in a plug-in cartridge, and Do-It!, a command line interpreter. Clint was also answering questions on the side about ACTION!, his 8-bit language and talking about his future projects.

Astra Systems was showing their complete line of disk drives, such as the Double-D, two true double side double density drive in a single case for the 8-bits, or the System HD+, which is 20.8 megabyte hard drive and a double side 3.5 inch floppy in the same box.

Atari Explorer Magazine was there with a display of issues all the way from the Warner Atari days to the present. The magazine is owned by Atari Corp., with David Ahl and Betsy Staples (from the now defunct Creative Computing) publishing it.

Charlie Bachand of ANALOG COMPUTING was selling copies of the current ANALOG and ST-LOG magazines and the new 8-bit Extra.

Looking Glass Software of Waterloo, Ontario was showing its ALICE Pascal, an easy-to-use, easy-to-understand version of Pascal which makes it easy, even for a beginner, to start programming. Among its many features, it helps the user input programs by providing templates of Pascal statements to be

filled in, helping to eliminate syntax problems. It fully supports GEM applications.

Desktop Publishing was represented by two of the major players, Migraph, with Easy Draw, and Progressive Computer Applications with Graphic Artist. Both programs were very impressive.

Alpha Systems was displaying their computer graphics products such as ComputerEyes, Magniprint, and Power Print. They had a huge poster of Winston Churchill produced by Power Print.

Michtron was showing its complete line of ST programs including their newest, Match Point, Karate Kid II, and the new GFA Basic.

Logic Ware was presenting its Prolog artificial intelligence systems which have previously been available for mainframes and IBM PC systems, and are now available for the ST.

ICD had a display of its 8-bit products including the US Doubler, the P:R: Connection, Multi-I/O, the 80 Column Adaptor, R-Time 8, and SpartaDos.

The Computer Service Group, a Buffalo based computer repair and supply company, had a demonstration of Tom Hudson's CAD 3-D System and Stereotek 3-D Glasses.

Several hardware and software dealers were at the show. Best Electronics was selling hard-to-find repair parts. Cal Com, Inc. and the Buffalo Computer Center were selling hardware and software items.

Wizztronics was showing their Midi Max interface for the 8-bit line.

Several user's groups were displaying their newsletters, disk libraries, and trading discussions about common problems and concerns. Some of the groups were exchanging the best of their public domain libraries. Among the groups represented were the Genesee Atari Group from Michigan, the Michigan Atari General Information Conference, Atari Computer Owners of Rochester, NY, Toronto Atari Federation, Spectrum Atari Group of Erie, and the host group, the Western New York Atari User's Group.

I was disappointed that some of the big players in the Atari world didn't show up, like David Small with the Magic Sac, or Bill Wilkinson from OSS. But I was happy to be able to chat with Neil Harris, Landon Dyer, and Art Morgan from Atari Corp., Charles Bachand and Lee Pappas of ANALOG Magazine, and Bob Retelle, SIGOP of the Atari SIG on GEnie.

I noticed that there was almost no support for the 8-bit lines except for ICD, Wizztronics, Best Electronics, and Astra. The user group booths did a booming business in 8-bit public domain

software, and many 8-bit questions were being answered by user
group members.

Subject: 6502 vs 68000
To: info-atari8@score.stanford.edu
X-Original-To: info-atari8@score.stanford.edu, 2FK8ALINE

In his message of 23 Apr 87 John Sangster writes that a 1.8 MHz
6502 might beat an 8.0 MHz 68000 in certain tasks. This is not true.
It is true that the quickest 6502 instruction is only 2 clock cycles,
but it is NOT true that the quickest 68000 instruction is 14. In fact,
the fastest 68000 instruction is but 4 cycles long - the average instruction
is around 12-14 cycles.
Compare this to the 6502's AVERAGE of about 4-5 cycles per instruction
(only CLC, INY, etc. take 2 cycles). At about 4 times slower than the 8.0 MHz
68000, NOTHING is faster on a
6502. I do agree that the 8 bit
machines have many virtues, and I love my 6502 Atari 800, but the 68000
is much more powerful, even if more
complex. One more point: the 6502 accesses memory every clock cycle,
while the 68000 takes a full 4 to do
so. This gives the 6502 a few advantages, but it still cannot outperform
the 68000 unless the clock speeds are much closer to each other.

-Eric Greene

390. ACTION! assistance...

Newsgroup: comp.sys.atari.8bit
Date: 1987-04-28 02:08:36 UTC
From: jhs@MITRE-BEDFORD.ARPA.UUCP
Message-ID: <8704280208.AA07928@mitre-bedford.ARPA>
Source record: 117644

I have just started writing in ACTION!, so pardon the dumb questions, but can anyone tell me if there is a way to read a block of bytes from a device in ACTION! without taking them one at a time?

Specifically, GetD(channel) returns one byte, InputBD(channel) also returns one byte, and (I assume) InputMD(channel, buffer, maxchars) inputs groups of characters all right, but terminates input on an EOL character. Or does it? What I want to do is to read in a specified number of characters, except if End Of File occurs during the attempt, I want to know how many characters were actually read before that happened. This can be done easily in assembly language -- it is precisely what CIO will do -- but I wonder if there is a way to do it in ACTION, other than doing a CIO call in a "code block" or subroutine call.

Any help will be greatly appreciated.

Thanks,
-John Sangster / jhs@mitre-bedford.arpa

391. Action! versions, etc.

Newsgroup: comp.sys.atari.8bit
Date: 1987-04-29 19:01:30 UTC
From: cel@CITHEX.CALTECH.EDU
Message-ID: <870429120112.043@CitHex.Caltech.Edu>
Source record: 117645

I've seen postings about Action! bugs and problems, but I've never been
sure what version my cartridge is. Is there any easy way to tell?
(Now just watch, it's printed somewhere obvious that I never checked, right?)

Also, ran across this one:

```
FOR I = 130 TO 1 STEP -1 DO
PRINTE("It works!!!!!")
OD
```

not working, because negative steps are a no-no, which isn't mentioned in
the manual. You can always work around it, but I wondered whether a more
recent release has fixed some of these things.

I too would like to know if there is a way to see what version of the cartridge I have. As for bug sheets OSS sells them for something like $5.00, they will also upgrade your cartridge for about $20.00.

393. Re: 68000 at 8 MHz versus 6502 at 1.76 MHz...

Newsgroup: comp.sys.atari.8bit
Date: 1987-04-30 17:57:16 UTC
From: jhs@MITRE-BEDFORD.ARPA.UUCP
Message-ID: <8704301757.AA03883@mitre-bedford.ARPA>
Source record: 117647

Aha! A good argument is developing... Eric Greene writes:
>the fastest 68000 instruction is but 4 cycles long - the average instruction
>is around 12-14 cycles. Compare this to the 6502's AVERAGE of about 4-5
>cycles per instruction (only CLC, INY, etc. take 2 cycles). At about 4 times
>slower than the 8.0 MHz 68000, NOTHING is faster on a 6502.

I hate to be stubborn (actually I LOVE to!) but Eric's own figures tend to
support my claim, at least to the extent that there are some tasks for which
there wouldn't be a vast difference in speed between a 6502 and a 68000.
If we compare AVERAGE times, based on Eric's figures, then the average time
per instruction for the two machines would be:

```
8-MHz 68000 1.76-MHz 6502
-------------------------------------------------------------

13 cycles (avg) 4.5 cycles (avg)
------------------ = 1.625 usec ------------------ = 2.556 usec
8.0 MHz clock 1.76 MHz clock
```

for a 1.573:1 advantage in favor of the 68000. This is considerably less
than the 4.5:1 ratio of the clock speeds or the "4 times faster" that Eric
alludes to. Probably much of the power of the 68000 comes from getting more
power per instruction rather than more instructions per second.

-John Sangster

394. Re: Is Atari killing the 8 bit?

Newsgroup: comp.sys.atari.8bit
Date: 1987-04-30 22:14:04 UTC
From: conklin@msudoc.UUCP
Message-ID: <1404@msudoc.UUCP>
Source record: 117648

I have a question, maybe someone from Atari can answer it, or maybe not. Is Atari purposely killing the 8-bits?

This question is, for the most part, brought on by the recent "high" prices put on the XE machines. Coupled with the already low ST prices it's obvious that the decision to go with either an XE or an ST is being made for the buyer. Other things that seem telltale are A.) The "game" title was slapped on the new XE machine, B.) The 3.5" drive and 80 column card do not exist. (Sorry gang, but unless I can _buy_ it, it doesn't exist. That's only fair. I dont buy things with promised money, and I can't purchase promised products.) C.) When ICD wanted more Parallel bus information to build the MIO box, they had to sign non-disclosure agreements. A _FAR_ cry from the open-architecture of Atari past which even distributed the source code to the OS, D.) Atari's recent telling the guy who did the ST's 8-bit emulator that he couldn't touch the OS code.

None of these events are the actions of a company with an interest in the 8-bit's future. That's fine, since they aren't making as much on the 8bit as they are on an ST, but I'd like to know if this is the committed direction. I, and something like 2 or 3 million other people have hundreds (or thousands!) of dollars tied up in 8-bit hardware, and would like to think that if Atari is no longer interested in marketing the machine, they would at least release it to the public domain to allow third party small time vendors support the existing owners of the machine or build compatible upgrades. Like the Commodore-128 or the Coco-3, a new machine that would only really interest existing owners, but would give them a 'full power' machine that they can keep their existing software and periperhals going on.

In article <1404@msudoc.UUCP>, conklin@msudoc.UUCP (Terry Conklin) writes:
> The 3.5" drive and 80 column card do not exist.
> When ICD wanted more Parallel bus information to build the MIO box,
> they had to sign non-disclosure agreements.

As for the 80 column card I saw one working at the Allentown Atari Expo! Recently there was a posting on GEnie from one of the ATARI Base SYSOPS concernig the XEP-80. He said it is in production. He didn't say when it should be out. Also the 1200baud modem it getting ready to come out. As for the 3.5" drive I don't remeber hearing an OFFICIAL announment just a lot of rumors.

Now the non-disclosure agreement is a standard form for all companies. Just because the old Atari didn't make people sign them doesn't mean the NEW Atari should do the same. All the agreement says is that the info we give is not to be given out. Now I'm sure if you had a valid reason for the info they would be glad to give it you.

I really don't think ATARI is killing the 8bit. Things just take time. There are new version of AtariWriter Plus coming out for the XEP-80. Also if you think they're killing it, how about giving some suggestions. All I've seen is complaints!

397. Action!

Newsgroup: comp.sys.atari.8bit
Date: 1987-05-01 14:16:57 UTC
From: curzon@kaoa01.dec.com
Message-ID: <9632@decwrl.DEC.COM>
Source record: 117651

Chuck Lane, cel@cithex.bitnet, writes with some questions about Action!, the "premier" compiled language for the 8 bit Atari. Also John Sangster had some questions, and no doubt some other new Action! users will be interested in this.

Bruce Langdon who used to contribute a lot of Action! code and hints to this newsgroup sent me a lot of material. I will post some of it here--

1) reply on negative steps in DO loops, from the now-defunct Action! BBS written by the author of Action!, Clint Parker. WHILE constructs will let you use negative steps, and Clint explains why DO doesn't allow negative steps.

2) Action! bug sheet number 3; part 2 of this bug sheet tells how to identify the version number of your cartridge.

```
------------------------------------------------------------------------
#: 108 size: 304
Sb: re: #105 - Negative STEPs
Fm: 1 SYSOP

#108 23:14:27 15-May-84

Warren,
No, that isn't the problem. The problem has to do with the code
generated for the ending condition. It is different for positive and negative
step sizes. There is no way to generate it for both cases at compile time
without making the FOR loop code much larger and slower.

- Clint

------------------------------------------------------------------------

ACTION! BUG SHEET #3 - part 1

This document supercedes the previous
two bug sheets published for ACTION!

November 6, 1984

-------------------------------------

GENERAL INFORMATION

Before getting to the bad stuff (the
bugs), here are some goodies about
```

ACTION! which we would like to pass on to you:

ACTION! BULLETIN BOARD

In order to speed the distribution of ACTION!-related information, Clinton Parker (author extrordinaire of ACTION!) has set up a bulletin board system. His company, Action Computer Services, is located in Rochester, New York, and you may try calling his bulletin board at
(716) 235-3394
and hit [RETURN] when asked for a password.

Clinton welcomes comments, suggestions, and praise. Complaints and their perpetrators will be ignored. That is, of course, our joke. But please, if you must offer criticism, keep the remarks construc-tive. And remember that OSS is responsible for distribution, etc. Clinton is the author and is (we feel) generous in making himself so accessible.

TIPS ON TEMPS

The magazine article titled "Lights, Camera, Action!" (by Dave Plotkin) which appeared in the July issue of ANTIC featured a set of routines to facilitate writing ACTION!-based interrupt handlers.

The article gave the listings for two routines (more properly, two DEFINEs) named "SaveTemps" and "GetTemps". These routines are adequate only if no math beyond addition and subtraction is performed in the interrupt service routine. The following versions of these two routines will work properly in the more general case:

Make the following DEFINEs in your program before you declare your interrupt routine (comments may be

```
omitted-- they exist only for clari-
fication):

DEFINE SaveTemps=
"[
$A2 $07 ; LDX #7
$B5 $C0 ; LOOP LDA $C0,X
$48 ; PHA
$B5 $A0 ; LDA $A0,X
$48 ; PHA
$B5 $80 ; LDA $80,X
$48 ; PHA
$B5 $A8 ; LDA $A8,X
$48 ; PHA
$CA ; DEX
$10 $F1 ; BPL LOOP
$A5 $D3 ; LDA $D3
$48 ; PHA
]"

DEFINE GetTemps=
"[
$68 ; PLA
$85 $D3 ; STA $D3
$A2 $00 ; LDX #0
$68 ; LOOP PLA
$95 $A8 ; STA $A8,X
$68 ; PLA
$95 $80 ; STA $80,X
$68 ; PLA
$95 $A0 ; STA $A0,X
$68 ; PLA
$95 $C0 ; STA $C0,X
$E8 ; INX
$E0 $08 ; CPX #8
$D0 $EF ; BNE LOOP
]"

Use these routines inside your
interrupt routine as follows:

; Your interrupt routine.
PROC InterruptRoutine()
; Local declarations, if any.
BYTE a, b, c, etc.

; First line of code within
; procedure
SaveTemps

... ; Your interrupt
; code goes here.
```

```
GetTemps ; Last line of code
; within procedure.
[$6C OldVBI] ; A special way to
; end for VBIs- see
; below.
```

For example, the following program will set up the routine ChangeColor as a vertical blank interrupt routine (hit the START key to exit the program):

```
DEFINE SaveTemps=
"[ $A2 $07 $B5 $C0 $48
$B5 $A0 $48 $B5 $80
$48 $B5 $A8 $48 $CA
$10 $F1 $A5 $D3 $48 ]"

DEFINE GetTemps=
"[ $68 $85 $D3 $A2 $00 $68
$95 $A8 $68 $95 $80 $68
$95 $A0 $68 $95 $C0 $E8
$E0 $08 $D0 $EF ]"

CARD OldVBI ; Will hold previous
; contents of vertical
; blank interrupt
; vector.

; This procedure will change the
; background color to random values.
; The main routine will set up this
; code to operate during the
; deferred vertical blank interrupt.
PROC ChangeColor()
BYTE hue, lum

SaveTemps
hue = Rand( 16 )
lum = Rand( 16 )
SetColor(2,hue,lum)
GetTemps
[ $6C OldVBI ] ; Vertical blank
; interrupts must end
; like this ($6C is a
; 6502 indirect jump
; instruction).

PROC Test() ; Main routine
BYTE critic=$42, ; Critical I/O flag
console=$D01F ; Console key
; hardware location
CARD VBIvec=$224 ; Deferred vertical
```

```
; blank interrupt vector

; You must install a VBI
; routine like this:
critic = 1
OldVBI = VBIvec
VBIvec = ChangeColor
critic = 0

; ChangeColor is now running
; as the vertical blank interrupt
; routine-- since our mainline
; code has nothing more to do,
; we just go into a loop waiting
; for the START key to be
; pressed.
WHILE console&1
DO
OD

; Now turn off the VBI routine.
critic = 1
VBIvec = OldVBI
critic = 0
RETURN

This method of saving and restoring
ACTION zero page variables may also
be used to write BASIC machine
language subroutines in ACTION! Your
main ACTION routine should then have
SaveTemps as the first executable
line, and GetTemps as the last
executable line before the RETURN
statement.

actbug2 508119184 302 52 100600 10553 `
ACTION! BUG SHEET #3 - part 2

-----------------------------------

BUGS IN THE ACTION! CARTRIDGES

The following is a list of all bugs
we currently know exist in the
ACTION! cartridge. We list these
bugs separately from those in the
RunTime library and/or the PAD disk
or ToolKit, which occur in following
pages. Each bug is described in
detail and, when possible, bug fixes
are given. Many of these bugs deal
only with specific versions of
```

ACTION!. To find out which version
of ACTION! you own, type the
following from the ACTION! monitor:

?$B000 [RETURN]

Below is an actual copy of what
printed following that command for
one of our cartridges.

```
45055,$B000 = 0 $0730 48 1840
^
```

To find out the version number, look
at the character to the right of the
equals sign (here printed with a
caret under it). The "0" in this
case implies that the cartridge is
version 3.0. If yours has a "6", you
own version 3.6, etc. As of the date
of this bug sheet, the current
cartridge version is 3.6.

1. OFFSETS -- Using a TYPE
declaration will generate a
spurious error whenever the code
offset (contents of location $B5)
is non-zero.

Affects: All versions of the
cartridge to date. (Presumably
only noticed if using RunTime
disk, though.)

Fix: Make all TYPE declarations
before changing the code offset.

Example:

```
; Beginning of program --
; First, declare TYPEs
TYPE IOCB =
[
BYTE Id, Devnum,
Command, Status
]

; Then, if desired,
; change offset
SET $B5 = $1000
; example: offset=4096
```

2. OFFSETS -- Using a code offset
greater than $7FFF (i.e., a

negative offset, if you consider
it to be of type INT) causes the
compiler to generate improper
code.

Affects: All versions,
especially when used with the
RunTime disk.

Fix: No direct fix, but you may
use the relocator program
described later in this document
(which is also usable with
assembly language).

3. ATARI DOS -- Exiting to Atari DOS
from ACTION! can cause a system
crash if DUP.SYS is not present
on the disk in drive 1.

Affects: All versions, but only
when used with Atari DOS.

Fix: Use DOS XL (or be careful
when exiting to DOS).

4. ARRAYS AND ELSEIF -- We have just
learned that there is a
relatively obscure bug in ACTION!
related to the use of ELSEIF. In
particular, statements similar to
the form
ELSEIF a(i) = 0 THEN ...
(where a is an ARRAY and i is a
CARD OR INT), or statements like
ELSEIF p^ = 0 THEN
(where p is a POINTER) produce
incorrect code.

Affects: All versions

Fix: There is no direct fix at
this time. The best way around
the problem seems to be to code
something like this:
t = a(i) ; t is an INTEGER
...
ELSEIF t=0 THEN ...
This works properly.

5. WRITING OBJECT FILES -- If a
monitor Write command fails
because of a disk error (e.g.,

disk full, 162, or device done, 144), the IOCB is not properly closed. If the disk is changed before another disk operation is performed, the new disk can have invalid data written to it.

Affects: All versions

Fix: If you get an error when writing an ACTION! object file, type the following command to the monitor:
X Close(1) [RETURN]
You can then erase the file which caused the error.

6. HEX ARRAY SIZES -- Hexadecimal values as array dimensions cause incorrect code to be generated.

Affects: All versions

Fix: Use decimal array dimensions.

7. TYPE POINTER ARGUMENTS -- PROC/FUNC declarations with record pointer arguments other than the first don't compile correctly. For example, the following code generates an error 7 (invalid argument list):
TYPE REC=[...]
...
PROC Test(BYTE x, REC POINTER p)

Affects: All versions

Fix: Omit the comma in the argument list for the PROC/FUNC, as in:
PROC Test(BYTE x
REC POINTER p)

As this is just a temporary fix, it may not work in future versions, but the correct declaration (with the comma) will.

8. MONITOR LOCKUP -- Typing the
following command from the
monitor will lock up the system:
R* [RETURN]

Affects: All versions

Fix: Don't do it! If you do
type that command, hit [RESET]

9. PADDLE FUNCTION -- The Paddle
function does not work properly
in all versions of the ACTION!
cartridge.

Affects: Versions 3.0 to 3.5

Fix: Make the following
declaration in your program:
BYTE ARRAY Paddle(4) = 624

10. SOUND ON CHANNELS 3 AND 4 -- If
you use a Sound() procedure call
after having done any disk I/O,
sound channels 3 and 4 will
remain silent. This is because
Atari's OS does not reset some of
the serial control registers
completely.

Affects: Versions 3.0 to 3.5

Fix: Type in and use the
following procedure. You should
call this before doing any
Sound() calls and/or in place of
any SndRst() calls:

```
; Contributed by Michael Ross
PROC SoundOff()
BYTE AudCtl = $D208,
SSKCtl = $232,
SKCtl = $D20F

SSKCtl = 3
SKCtl = 3
AudCtl = 0
SndRst()
RETURN
```

11. TYPE FIELDS AS PARAMETERS --
Using fields of TYPEs as
parameters to PROCs or FUNCs
generates incorrect code. For
example,

```
MoveBlock( rec.addr1,
rec.addr2, length )
```

Affects: Versions 3.0 to 3.5

```
Fix: Assign the TYPE field to a
temporary variable and pass that
as a parameter:
temp1 = rec.addr1
temp2 = rec.addr2
MoveBlock(temp1,temp2,length)
```

```
12. SASSIGN PROBLEMS -- SAssign does
not work properly when the source
string has a length of zero.
```

Affects: Versions 3.0 to 3.5

```
Fix: No fix available at this
time.
```

```
13. CARD FIELDS IN TYPES -- Accessing
CARD fields of TYPEs generates
incorrect code.
```

Affects: Versions 3.0 to 3.2

```
Fix: No fix available at this
time.
```

```
14. MOVEBLOCK PROBLEMS -- MoveBlock
does not move more than 256 bytes
of data.
```

Affects: Versions 3.0 to 3.2

```
Fix: No fix at this time. You
could write an ACTION! routine to
do the equivalent.
```

```
15. CONTROL-SHIFT RETURN -- Using
[CS] RETURN to split a line into
two lines generates garbage in
the second line.
```

Affects: Versions 3.0 and 3.1

```
Fix: No fix available, but not a
disastrous problem.
```

```
16. DIVISION ERRORS -- On old
cartridges, neither the "/"
operator nor the "MOD" operator
works properly under certain
conditions.
```

Affects: Versions 3.0 and 3.1

Fix: Insert the following code
into your program before any of
your own PROCedure or FUNCtion
declarations (this can be done
easily using INCLUDE):

```
; Copyright (c) 1983 by
; Action Computer Services
;
; Permission is granted to
; duplicate and/or distribute
; the contents of this file
; to ACTION! users. Copies of
; this file may not be sold or
; used for monetary gain.

PROC DivI=*()
[$20 $A06C $85 $86 $A2 $10
$26 $82 $26 $83 $26 $86 $26
$87 $38 $A5 $86 $E5 $84 $A8
$A5 $87 $E5 $85 $90 $04 $85
$87 $84 $86 $CA $D0 $E5 $A5
$82 $2A $26 $83 $A6 $83
$4C $A032]

PROC RemI=*()
[$20 DivI $86A5 $87A6 $60]

SET $4EA=DivI
SET $4EC=RemI
```

17. ERROR ROUTINE NOT INITIALIZED --
The address of the Error
PROCedure is not restored by
ACTION! if a user program has
changed it.

Affects: Versions 3.0 and 3.1

Fix: Make sure to restore the
original Error vector upon
exiting a program, if you changed
it.

18. COMPLEX EXPRESSIONS IN UNTIL --
Complex relational expressions in
an UNTIL statement generate
incorrect code. For example,

```
DO
...
UNTIL a>0 AND b=3
OD
```

Affects: Versions 3.0 and 3.1

Fix: Assign the expression to a
temporary variable and test that
variable, instead:

```
DO
...
temp = a>0 AND b=3
UNTIL temp
OD
```

19. BANK SWITCH BUG -- When loading
and running compiled ACTION!
object files from DOS, the system
can crash when using older
cartridges. This is because the
ACTION! library is not
accessible.

Affects: Version 3.0 only

Fix: Put the following program
lines at the VERY BEGINNING of
your main procedure (i.e., the
last procedure in your program):

```
BYTE bank = $D500
; This declares the variable
; 'bank' to reside at $D500.

bank = 0 ; This must be the
; first executable statement.
```

20. .COM PROGRAMS -- Running compiled
ACTION! programs as .COM files
under OS/A+ causes those programs
to execute twice.

Affects: All versions, but only
when using a version of OS/A+.
DOS XL is not affected.

Fix: Insert the following as the
first global variable you
declare:

```
BYTE RTS=[$60]
; This MUST be the first
; line in your program,
; aside from comments and
; SET commands.
```

21. PROC ADDRESSING -- Under certain
conditions, specifying the
address of a procedure (e.g., to

interface to a machine code
routine) causes ACTION! to
generate incorrect code which
could cause your program to
"hang".

Affects: Versions 3.1 and 3.4

Fix: Insert an empty code block
after the declaration of a
procedure whose address is
specified. For example:

```
PROC CIO = $E456() []
; An empty code block!
```

22. ERROR #3 -- If you get an ERROR 3
during a compile, the system
hangs when you return to the
editor.

Affects: All versions

Fix: Do not go to the editor
until you type the following line
to the monitor. This command
resets the ACTION! memory
pointer.

```
SET $E=$491^
```

23. STRING INPUT -- When using the
string input library functions
(InputS, InputSD, and InputMD),
there must be room in the string
for the termination EOL, even
though the resulting string
length will not include it.

Affects: All versions

Fix: Adjust your declaration
appropriately.

actbug3 508119182 302 52 100600 2292 `
ACTION! BUG SHEET #3 - part 3

BUGS IN THE ACTION! RUNTIME LIBRARY

We have found a few bugs in the
original version(s) of the RunTime
Library Disk. Fortunately, they are
all easy to fix. (The RunTime

```
library is independent of the
cartridge, so bugs affect all
versions.)

In the fixes given below, the portion
to be changed (to implement the fix)
is underlined. The rest of the line
remains the same. To make the fixes,
simply load the library file
containing the affected PROCedure,
edit, and save it back to disk.

1. Hex numbers are printed
incorrectly by PrintH and the %H
parameter of PrintF.

Fix: Change second line of CCIO:

PROC CCIO=*()
[$A386$A0A$A0A$AA$A3A5$9D$342 ...
--- ---

2. PrintBDE can cause a spurious
compile time error.

Fix: Change first line of
PrintBDE:

PROC PrintBDE =*(BYTE d,n)[$A0$0]
--
3. A minor error exists in ChkErr.

Fix: Change second line of
ChkErr:

PROC ChkErr=*(BYTE r,b,eC)
[$1610$88C0$8F0
$98$80C0$12F0 ...
---
4. If your program redefines a
library procedure (e.g., one
which declares its own version of
PROC Graphics), it will compile
with no errors using the
cartridge only (because declared
procedures take precedence over
built-in ones). However, since
the RunTime library uses this
same precedence trick to include
its own definitions of library
procedures, your program will
generate Error 6 (doubly defined
name) if you do not delete the
```

appropriate PROCedure (or
FUNCtion) from the RunTime
library before INCLUDEing it.

Fix: Make a custom version of
the RunTime library on a COPY
(please, only on a copy) of your
RunTime disk which does not
contain the routines you wish to
replace.

5. On page 17 of the Reference Guide
for the Runtime Package, the
DEFINE for ROM will cause
incorrect code if you use local
variables.

Fix: Use the following form of
definition, instead:

```
DEFINE ROM = "BYTE ZZQQJUNK
-------------
SET $680 = $E^
SET $B5 = $5800
SET $E = $682^"
actbug4 508119186 302 52 100600 8605 `
```

ACTION! BUG SHEET #3 - part 4

PROBLEMS WITH PAD

We will list the problems (and
solutions) regarding the Programmer's
Aid Disk here in reasonably compact
form.

1. BGET/BPUT PROBLEMS -- The BGet
and BPut routines in the IO.ACT
file do not work properly under
certain conditions. To fix this
bug, replace the BGet and BPut
routines with the following
ACTION! code:

```
;*********************************
;Burst (Block) I/O routines to do
;quick disk I/O, utilizing a call
; to CIO
;*********************************

PROC CIO=$E456( BYTE areg, xreg )

;*********************************
```

```
CARD FUNC Burst( BYTE chan, mode,
CARD addr, buflen )

TYPE IOCB=[BYTE id,num,cmd,stat
CARD badr,padr,blen
BYTE a1,a2,a3,
a4,a5,a6]

IOCB POINTER iptr

chan ==& $07
iptr = $340+(chan LSH 4)
iptr.cmd = mode
iptr.blen = buflen
iptr.badr = addr
CIO( 0, chan LSH 4 )
RETURN( iptr.blen )

;*******************************

CARD FUNC BGet( BYTE chan,
CARD addr, len )
CARD temp

temp = Burst(chan,7,addr,len)
RETURN( temp )

;*******************************

PROC BPut(BYTE chan,
CARD addr,len)
Burst( chan, 11, addr, len )
RETURN
```

2. PRINTF -- The PRINTF routine has a bug which was reported and fixed in the Spring, 1984 newsletter. In the file PRINTF.ACT, use the ACTION! editor to find

```
args ==+ s
```

and change it to

```
args ==+ 2
```

3. PLAYER/MISSILE GRAPHICS -- Because S: uses some memory just below the display list (undocumented), our method of finding the base address for Player/Missile Graphics needs a slight revision. Use the ACTION! editor with the file PMG.ACT to find

```
PM_BaseAdr=(HiMem-
```

```
PM_MemSize(mode))
&PM_AdrMask(mode)
and change it to
PM_BaseAdr=(HiMem-
PM_MemSize(mode)-$80)
&PM_AdrMask(mode)
```

```
4. If you use the PMMove procedure
and specify a vertical movement
of zero, the horizontal movement
does not take place (it should).
To fix this, change the lines in
PMG.ACT which read
IF deltay=0 THEN
RETURN ; do nothing
FI
to the following:
IF deltay=0 THEN
; do horizontal anyway
PMHpos(n)=x
RETURN
FI
```

```
5. PLAYER/MISSILE GRAPHICS -- The
documentation for PMG.ACT states
that you may read the contents of
PMHpos to find the horizontal
position of a player or missile.
This is simply not true. PMHpos
is a set of write-only hardware
registers. (Note that in the
ToolKit we have added a shadow
array and changed the name of the
hardware registers, so this works
correctly. If you wish, you
could consider doing something
similar on your PAD.)
```

```
6. REAL NUMBER ROUTINES -- There are
two discrepancies in PROCedure
names in the REAL.ACT library as
compared to the REAL.DOC
documentation, as follow:
Name in .DOC Name in .ACT
StrR RealToStr
ValR StrToReal
We suggest that you change the
source code in REAL.ACT to
reflect the names given in the
documentation (rather than vice
versa), since this makes the
```

names appear compatibile with the
library's other number-string
conversion routines.

7. REAL NUMBER ROUTINES -- In that
same area, the routine RealToStr
(or should that be StrR?) needs
to change the line which reads
ptr=LBuff
to the following:
ptr=InBuff

8. ALLOC.ACT -- The free list
pointer may not be set up
properly. Also, when freeing a
block, right adjacency is not
handled properly if left
adjacency has already been found.
Fix these problems as follows:

In the PROCedure Free, after the
line reading:
last.size==+nBytes
insert the line:
target=last

Also, in the same procedure,
change the line reading:
IF target+nBytes=current THEN
to read:
IF target+target.size
=current THEN

In the PROCedure AllocInit,
replace the line reading:
FreeList.next=p
with the following lines:
FreeList=p
p==+4
FreeList.next=p

TOOLKIT TROUBLES

It's hard to believe that a product
as new as the ACTION! ToolKit can
already have bug reports. Sigh.
Anyway, there are already three
versions of the ToolKit. Version 1
has 31 free sectors (when you list
its directory). Version 2 has fewer
free sectors and the second line of

the file MUSIC.DEM reads ";Version 2". On version 3, the file ABS.ACT starts with the version number. This last convention will be followed in future versions. The comments here are organized by affected version(s).

VERSION 1 ONLY

1. I/O ROUTINES -- The manual describes a routine called Format (in the IO.ACT library), but no such procedure exists on the disk. However, the routine is there--it's just called Init instead. You should change your disk to match your manual.

2. MUSIC.DEM -- The program called MUSIC.DEM will not work as is on older 400/800 machines. This is because it uses a call to Graphics(15), which is only available on XL machines. You may change the program to use Graphics(8) with no effect except that the true colors of mode 15 become artifact colors in mode 8 instead.

VERSIONS 1 AND 2

1. REAL ROUTINES -- There are two discrepancies in PROCedure names in the REAL.ACT library as compared to the REAL.DOC documentation, as follow:

Name in .DOC Name in .ACT
StrR RealToStr
ValR StrToReal

We suggest that you change the source code in REAL.ACT to reflect the names given in the documentation (rather than vice versa), since this makes the names appear compatibile with the library's other number-string conversion routines.

2. SORT ROUTINES -- There are four discrepancies in PROCecure names

in the SORT.ACT library as
compared to the SORT.ACT
documentation, as follows:

Name in .DOC Name in .ACT
SortB BSort
SortC CSort
SortI ISort
SortS SSort

Please change your disk file to
agree with your manual.

3. PRINTF -- The PRINTF routine has
a bug which was reported and
fixed in the Sprint, 1984
newsletter. In the file
PRINTF.ACT, use the ACTION!
editor to find
args ==+ s
and change it to
args ==+ 2

VERSIONS 1, 2, AND 3.

1. ALLOC ROUTINES -- The manual in-
dicates that the procedure
AllocInit requires that you pass
it the address of the first free
byte of memory (because Alloc
"dispenses" memory from the first
free byte through the top of
memory, as correctly described in
the manual). However, since you
MUST follow the procedure
described in the introduction to
ALLOCATE.ACT (that is, you must
declare in your program a CARD
called EndProg and use the
command
SET EndProg=*
after compiling), the parameter
to AllocInit is not really needed
and so has been eliminated.
(AllocInit uses EndProg just as
Alloc does.) If you pass a
parameter to AllocInit, it will
be ignored.

2. WARP.DEM -- No mention is made in
the Toolkit manual that this file
can only be run when compiled

from disk (unless you are using
DOS XL to gain extra memory).
WARP.DEM is just too big for
ACTION! to hold both the source
and object in memory at one time.

3. ALLOCATE.ACT -- The free list
pointer may not be set up
properly. Also, when freeing a
block, right adjacency is not
handled properly if left
adjacency has already been found.
Fix these problems as follows:

In the PROCedure Free, after the
line reading:
last.size==+nBytes
insert the line:
target=last

Also, in the same procedure,
change the line reading:
IF target+nBytes=current THEN
to read:
IF target+target.size
=current THEN

In the PROCedure AllocInit,
replace the line reading:
p=EndProg
with the following lines:
FreeList=EndProg
p=EndProg+4

actbug5 508119191 302 52 100600 7686 `
ACTION! BUG SHEET #3 - part 5

ACTION MANUAL ERRATA

First of all, you need to know which
version of the manual you have. If
Part III is the Language, then you
have the first version of the manual.
Otherwise, you have the second
(newest) version. Unfortunately,
both manuals contain content as well
as typographical errors. We'll skip
the typos and concentrate on the
content errors, since typos don't
impair your understanding of the
language (although you may wonder

where we learned to spell).

VERSION 1 ERRATA:

PAGE ERROR
2 In the last paragraph, it says
that the library is on the
disk. This is not true. It's
in your cartridge.

23 Under the description of
<BACK-S>, the comparison with
the Atari screen editor is
exactly reversed. If you are
in REPLACE mode, this key
works as in the Atari editor.

26 Under <CTRL><SHIFT>T, it says
you may not use lower-case
characters as tags. This is
untrue.

48 In the NOTE preceeding 4.3,
you should add "The *, /, and
MOD operators result in an
implied INT type. For this
reason, multiplication,
division, and modulus of large
CARD numbers does not always
work properly."

49 Section 4.4 says that you may
only have one special operator
in a complex relational
expression. This is untrue.
For example, the following is
perfectly legal:

(x=7 AND y#10) OR z<100

82 Section 6.2.3 implies that you
may not use a function as a
procedure. This is not true.
You may call a function as
though it were a procedure,
but the value returned from
the function is ignored.

97 Section 8.1.1 states that you
may either initialize a
POINTER to an address or give
it a value. Only the second
is possible, and you should

use this form:

BYTE POINTER x=<value>

Not this:
BYTE POINTER x=[<value>]

99 In example #1 there are two
PrintF statements which have
"ptr" as one parameter. These
should be "bptr", not "ptr".

101 In the last example of ARRAY
declaration (BYTE ARRAY
tests(5)...), the dimension is
overruled by the
initialization options, and so
its dimension is only three.
To fill only the first 3 of 5
elements, do the following:

BYTE ARRAY tests(5)=
[4 7 18 0 0]

104 In example #3 you see the
program line "PrintE(b)".
This should read
"PrintE(barray)".

108 Section 8.3.1.2 states that
you can initialize the fields
of a record when you declare
it. This is untrue; you may
only initialize its address.

110 The program line "rec.level =
InputB()" should read
"rec.level = GetD(7)".

112 Same as previous error.

115 Same as previous error.

112 The program line
"continue=InputB()" should
read "continue=GetD(7)"

120 The program line
"mode=InputB()" should read
"mode=GetD(7)", and the
program line "PrintE(name)"
should read "PrintE(nameptr)".

115 Same as previous error.

122 The program line
"incctr=chgclr" should read
"incclr=chgclr".

142 Section 5.3 states that you
should not use channel 7.
ACTION! uses this channel to
get characters from the
keyboard, and you may use it
to do this also. However,
don't close this channel or
alter its configuration in any
way.

153 The example of declaring an
ACTION! procedure at an
address is wrong! If you do
this, the internal pointer to
the procedure will point to
the specified address, but the
code generated by the
procedure will not be there.
Instead, it will be in with
your main code. Use procedure
and function addressing ONLY
to call machine language
routines.

161 Where the table of contents
lists the routines in section
2.3, it should read:

PrintBD NOT PrintDB
PrintCD NOT PrintDC
PrintID NOT PrintDI

162 Where the table of contents
lists the routines in sections
6.7 and 6.8, it should read:

PeekC NOT CPeek
PokeC NOT CPoke

165 Error in section 2.3. See
changes for pg. 161 and make
similar corrections.

179 Section 6.4 states some
information concerning the
results of misusing the SCopy
routine, detailing that the
routine does string trucation,
etc., to make the procedure
work. This is not true. You

must make sure that the
strings are compatible in
size.

181 Section 6.8 states that the
parameters to Poke and PokeC
consist only of an address.
Instead, they consist of an
address and a value, as
follows:

Poke(<address>,<BYTE value>)
PokeC(<address>,<CARD value>)

182 Section 6.11. MoveBlock will
move a maximum block of 256
bytes in versions 3.0 to 3.4
of ACTION! Versions 3.5 and
up will move any number of
bytes.

191 Some error numbers are wrong.
The corrections are:

14 Out of Space
15 Missing DO
19 Missing OD
24 Illegal FOR statement
26 Nesting Too Deep
27 Illegal TYPE reference
28 Illegal RETURN
128 BREAK key abort

Also, error 62 is error 61,
and 54 & 56 do not exist.

197 In the PrintF statement, %D
should be changed to %U.

VERSION 2 ERRATA:

PAGE ERROR
38 Section 2.7, paragraph 3. The
last sentence states that you
can RUN compiled ACTION!
programs from disk. This is
untrue. The RUN command will
only compile and run ACTION!
source files. Use DOS to run
compiled object files.

39 The last RUN example (RUN
PrintE()) will not work, since

RUN expects a file name. Use
the "Xecute" command instead.

63 In the TECHNICAL NOTE
preceeding section 4.3, "*"
should be changed to "*, /, or
MOD".

126 The last assignment on the
page makes newrecord point to
the current record in the
array, not the end of the
array.

132 The program line
"mode=InputB()" should be
changed to "mode=GetD(7)".

138 The program line "IF
sub(1)=str(ctr)" should read
"IF sub(1)=str(ctrl)".

163 The PutDE procedure requires
only a channel as a parameter,
and does not put out both a
character and a <RETURN>.
Rather, it puts out a <RETURN>
only.

172 In graphics mode 0 and all
text windows, color 1 is the
character luminance, color 2
is the background color, and
color 3 is unused.

174 In section 5.6, references to
the "lower right corner"
should instead be "lower left
corner".

180 Section 6.1.2 states some
information concerning the
results of misusing the SCopy
routine, detailing that the
routine does string
truncating, etc. This is not
true. You must make sure that
the strings are compatible in
size.

182 Section 6.11. MoveBlock will
move a maximum block of 256
bytes in versions 3.0 to 3.4

of ACTION! Versions 3.5 and
up will move any number of
bytes.
actbug6 508119194 302 52 100600 1251 `
ACTION! BUG SHEET #3 - part 6

ACTION OBJECT CODE RELOCATION PROGRAM

The program SIMPLREL.ACT on this BBS may be used to cause an ACTION! program to load and run at a different address than that address at which it was compiled. The same program will also work for assembly language object files, providing you also follow the given instructions.

The program takes two object files as input and produces a third file which will load and run at a desired address. The relocating program prompts the user for the two input files, which must have been compiled one page (256 bytes) apart. It then prompts for an output file name (the relocated file), the page number of the starting address of the first file, and the page number of the desired destination address. Both page numbers must be decimal values. For example, specifying 32 as the destination page will cause the output file to load at address 32*256 ($2000), not $3200.

See part V, "The ACTION! Compiler", chapter 2, page 144, for information on compiling programs to a specified address (Used to compile the two object files one page apart).

In order to use the relocating program, download SIMPLEREL.ACT and read the instructions therein.

400. Re: Ace C status and info

Newsgroup: comp.sys.atari.8bit
Date: 1987-05-01 17:20:33 UTC
From: btb@ncoast.UUCP
Message-ID: <2451@ncoast.UUCP>
Source record: 117654

the real C that I mentioned recently was an allusion to some work that steve kennedy has been doing with the dbc sources to extend them. i don't know what he plans to do with it when he gets it going, but he has an Atari simulator running on a Vax which has given him plenty of productivity to extend dbc... his problems, the last i talked to him, involved shrinking this improved C to fit in the Atari...

let's get on him to try to convince him to bring this out pd or sell it! he is adding structures and some other neat stuff.

the difference between what he has done and what Ralph Walden has done is that in the course of developing ACE C and Lightspeed C, Ralph added some nonstandard features to the C such as comments that cannot cross line boundaries and some other stuff. (I have also talked to ralph) don't get me wrong, ralph has done a very good job with several programs (including ACE C) for the Atari's, but isn't it time that we stand up and demand a standard (for once) language? i think so.

steve is smk on the net... i don't know his address at this moment.

401. Turbo BASIC's Public Domain status confirmed...

Newsgroup: comp.sys.atari.8bit
Date: 1987-05-01 18:08:06 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8705011808.AA06574@mitre-bedford.ARPA>
Source record: 117655

Users of Turbo BASIC should be pleased to have confirmation of the fact that Turbo BASIC is indeed a Public Domain package. The following is the most detailed reply I received from a recent query to the net on this point.

------- Forwarded Message
From: mcvax!nikhefh!n06@seismo.CSS.GOV (Jos Groenland)
To: jhs
Subject: Turbo basic

"Happy Computer" is a German montly magazine for home computing. The writer of Turbo Basic is Frank Ostrowsky who won a competetion with it (Program of the Year or something like that). Happy computer published the interpreter as a "type-in" program for the XL/XE in 1985. They have a 800 version as well, it was possible to order it. It was also possible to order the XL version of the interpreter (and later the Compiler as well) for a minimal amount of money, (i.e. disk & posting costs) in Germany. It was allowed to copy the programs freely, so it is public domain.

The USA representative of "Markt und Technik" publishing is:
M&T Publishing inc.
501 Galveston Drive
Redwood City CA94063
tel: (415) 366-3600
Perhaps you can ask them for more information.

I need to find a terminal program to use with my modem. It's not a direct connect and works at 300/1200 baud. I want to be able to download, upload and all that fun stuff. My one major restriction is that I only have 32K. I would prefer something in the PD or Freeware area. Any help would be appreciated.

403. graphics on the 8-bitters

Newsgroup: comp.sys.atari.8bit
Date: 1987-05-01 20:10:09 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8705012010.AA11370@mitre-bedford.ARPA>
Source record: 117657

I would appreciate a little tutorial from someone on the net who knows a lot about graphics, on the following subject:

What is the "correct" way to translate from ordinary geometric dimensions into pixel counts, to get undistorted screen images of geometric figures which exist "in the computer's mind"? I am specifically interested in the highest-resolution mode (Graphics 8?) which displays 320 pixels horizontally by 192 vertically. I note that this is exactly in the ratio 5:3, and is somewhat less than the full screen size in both directions. I also know from expert broadcast television sources that the TV "raster" (the whole thing, which one normally does not see because it extends beyond the edges of the consumer TV screen) is in the ratio 4:3. I also know that the vertical scan is 262.5 lines high, so the 192-line active area the Atari uses is 192/262.5 or about 0.73 of the full raster height. I am not sure what fraction of the horizontal scan line is represented by the 320 pixels, or equivalently, how many pixels there would be from edge to edge of the raster if the same spacing were used.

I would like to work with a monitor or TV which is set up correctly (4:3 for the whole raster) and get geometrically correct images from the Atari. Can I assume that one pixel spacing horizontally is the same distance as one pixel spacing vertically? If not, what correction factor should I use and how should I apply it?

Any (factual) help will be greatly appreciated.

A very kind and pious thought, but the fact that nobody (except Ian Chadwick, the author of "Mapping the Atari") has been able to get listings or documentation for the XL operating system would appear to be cause for disagreement with this.

405. Re: pd turbo basic interpreter for atari 800

Newsgroup: comp.sys.atari.8bit
Date: 1987-05-02 16:56:17 UTC
From: ssegan@dasys1.UUCP
Message-ID: <343@dasys1.UUCP>
Source record: 117659

In a recent message, jhs asked about urbo Basic-800. This is what I know:
Turbo Basic-800 -does- exist. Unfortunately, it is not very widely
distributed, as opposed to Turbo Basic XL. The Happy Computer message
refers to the developers of the program --- all Turbo modules are totally P/D.
[By the way, I know a local Bulletin Board that has Turbo Basic 800, but
the SysOp -doesn't want- to put it up!! :-( ]
As for ARC and ARCX, all I can say is to try the Translator.

406. ACEC questions

Newsgroup: comp.sys.atari.8bit
Date: 1987-05-04 21:11:43 UTC
From: greg@cvl.umd.edu
Message-ID: <2198@cvl.umd.edu>
Source record: 117660

Thanks to Fred Sullivan for posting the ACE C package! I've been hoping to get hold of a decent language utility for my 8-bit ever since I got it, but being a poor student, I couldn't afford the Kyan Pascal system, and there just didn't appear to be any C packages at all out for the 8-bit machines. Lightspeed sounds like a good implementation for development, but I'm not sure I want to buy an incomplete C compiler; one can get very used to conveniences like structures and multidimensional arrays.:) Maybe if enough of us tell Clearsoft that we want a full implementation, they will get one out. I was thinking I would have to learn about compiler design, and write one myself, but I really don't have the time.

Now for my queries: I can't get the 'pmdemo' program to run at all; it compiles, but all my attempts to link it and the graphics library (graphics.c) end with a spectacular bomb, lots of mixed graphics modes and a console lockup. Anybody get this working? Also, I was wondering if there is a way to prevent the compiled programs from blanking the screen upon exit. I appreciate any and all help.

407. 8 and 16 bit atari - some thoughts

Newsgroup: comp.sys.atari.8bit
Date: 1987-05-05 02:29:38 UTC
From: daryl@ihlpe.ATT.COM
Message-ID: <1726@ihlpe.ATT.COM>
Source record: 117661
Cross-posted to: comp.sys.atari.8bit,comp.sys.atari.st

I wanted to share some of my thoughts on where the 8 vs 16 bit atari machines is going.

I have owned an atari 8 bit machine since 1980 and have loved every minute of it. I am now at a crossroads, however, in upgrading. As background, I have an 130XE, 810 drive, monitor, and an MX80 printer. Consider the following data (near best price from magazines):

Upgrading the XE: ATARI ST (new):
SpartaDOS 3.2 $40 1040ST/mono $820
RTIME8 (clock) $50 Clock/cal $50
MIO (1meg) +20Meg HD $970 (ATARI) 20 Meg HD $650
MIDI (Hybrid Arts) $200 (midi built in)
----- -----
$1360 $1520

(Mono ST vs. Color XE is not totally fair, but read on)

I simply cannot bring myself to spending like that on a dead end machine. However, after giving it some thought, I concluded that the 8 bit machines ARE NOT DEAD. Why? They still do many things very well. Also I have noticed that a lot of 8 bit software is VERY CHEAP!

So here is where I think things are going based on my needs as a model (ha)

Keep the 8 bit machine. Let my child use it sometimes (he is currently 3). I went out and bought a second disk drive for it (a $130 1050) to eliminate the disk swapping head aches. I will continue to buy software for it since that is usually priced below the new machines. For example, recently I got
ARCHON II <$10
Miner 2049 <$5
Millipede $2.50
Can't beat that.

Get an ST. I intend on using it for synthesizer control and a genealogy data base project. If ATARI gets its TT act together, who knows? A sun (near) equivalent machine at home!

I leave you with this summary. The 8 bit machines are NOT dead, but the future holds limited interest and growth. The machine prices are getting so low that you cannot significantly expand an 8 bit for much less than an ST.

Comments are indeed welcome. I am not spending any money on these things yet until I have a chance to think about this for a while.

8 bits forever,
16 bits for the future too.

>language -- it is precisely what CIO will do -- but I wonder if there is a way
>to do it in ACTION, other than doing a CIO call in a "code block" or
>subroutine call.

The following routine is a real kluge, but it does what you want. I don't think that this a dumb question. xio was obviously intended to copy the BASIC command of the same name. This is quite unfortunate, since the result is to give the programmer access to only a part of the cio facility. It would have made much more sense to give the programmer full access to the cio functions. (As I am sure you've figured out, it is quite easy to write a procedure which does this. The record facility comes in handy in setting up the cio block.) I wasn't at all sure that this would work until I tried it.

```
proc get_bytes(byte channel,
byte length,
byte array buffer)
buffer(0) = length
xio(channel,0,7,0,0,buffer)
return
```

xio takes the length byte from the string and stores it in the byte count/ buffer length location in the cio block. In the above, the buffer must be a array of size length + 1, and length must be < 256. This is because Action! is expecting an ordinary Action! string. I don't think it is possible to make this work with longer buffers. If you set the buffer length entry in the cio block, xio will reset it with a high byte of 0. Also, I think that the only way to find out how many characters were actually read is to read the buffer length/byte count field directly from the cio block after the call to xio. Still, this might be useful if you know that the size of the file is a multiple of some number. Otherwise, it's probably worthwhile to do it from scratch, calling cio. I hope that this is helpful.

409. ARCX problems

Newsgroup: comp.sys.atari.8bit
Date: 1987-05-05 17:03:56 UTC
From: cel@CITHEX.CALTECH.EDU.UUCP
Message-ID: <870505095823.0a8@CitHex.Caltech.Edu>
Source record: 117663

I've been trying to get the ARCX program that was posted going on my
800, with only a certain amount of luck. The program as posted
uudecodes to a binary load file that looks like:

$FFFF binary file flag
$2416 - $4D38 part1
$0400 - $0510 part2
$02E0 - $02E1 starting address = $3000
$FF1A - $FFFF ?? all $FF's ??

the last segment won't load properly on my system, and it looks like a
control-Z followed by $FF's. I truncated the last piece, and the program
at least loads and starts running, asking for an archive file, and
doing a disk directory properly. When I uudecode JUMBO and have ARCX
work on it, it starts to extract ARC.COM,

(paraphrasing)
<Enter filename or + for directory>
>JUMBO.ARC
DRIVE #1
SCREEN OFF?: N
<Extracting ARC.COM> ... 196 bytes <squeezed>

and just hangs there. Checksums match for uudecoded JUMBO and ARCX when
uudecoded on my 800 and VAX/VMS, so I think they uudecoded okay. Are there
some system dependencies? I have a 48K `plain vanilla' 800, running
OSS's DOSXL. I've also tried Atari DOS 2.0, with the exact same results.

410. Disk drive questions

Newsgroup: comp.sys.atari.8bit
Date: 1987-05-05 22:35:00 UTC
From: jrd@STONY-BROOK.SCRC.SYMBOLICS.COM.UUCP
Message-ID: <870505183507.6.JRD@GRACKLE.SCRC.Symbolics.COM>
Source record: 117664

A couple of questions:

I've got a fairly old Astra 1620 disk drive, which has this annoying habit of writing bad sectors periodically. It seems to happen only when the machine's been reading from drive 2, and then goes to write on drive 1 immediately. Sometimes (not always) when that's been happening, a bad sector or two shows up right in the middle of the file on drive two that it was reading. Not nice. It seems to work fine if there's a delay between reading and writing. Has anyone ever seen this sort of lossage, and if so, what can I do about it?

Second question, which shouldn't come as a surprise in light of the first, is what recommendations does anyone have about disk drives these days? I'm looking for single/double density, dual disk models preferred.

Any information appreciated.

411. C on the Atari.

Newsgroup: comp.sys.atari.8bit
Date: 1987-05-06 15:36:35 UTC
From: jhs@MITRE-BEDFORD.ARPA.UUCP
Message-ID: <8705061536.AA23286@mitre-bedford.ARPA>
Source record: 117665

Did I miss the posting of Ace C to the net? I didn't see it go by, but am seeing messages of appreciation. Why, oh why, does my host have to pick the worst possible times to be down? (I know, Murphy's Law, of course.)

Could somebody re-post it or mail it to me directly? Thanks!

Also, can anybody comment on the following: It appears to me that ACTION! is MANY TIMES faster at compilation than any C compiler around. E.g., my wife, who has used C compilers on WANG's IBM-PC clones, about fell off her chair when she saw how fast ACTION! compiled a 2-page program -- around 0.75 second, as I recall, by the way. Now, it appears to me that ACTION! is a lot like C, and probably a C implemented with the same kind of approach would compile just about as fast. I understand that ACTION! also produces mind bogglingly efficient code. We will all have a chance to see how true this is if I ever finish my C version of uuencode and uudecode and we can compare with the Deep Blue C and BASIC/ML versions that now exist. My question is this: Would it be possible to implement C with ACTION! technology, and would it indeed run as fast and compile as fast as ACTION! does? If so, why doesn't somebody up and do this? (Clint Parker, where are you?!)

While I have the floor, let me also ask why in all these years nobody has come up with a standard for "relocatable object code" for the Atari? Usually when I ask people this, they say "it's hard to write relocatable code for a 6502". In my mind, that is the very reason that we NEED a relocatable object code format. This is not an executable format, but one which can easily be relocated to the desired memory segment and the absolute references filled in. What is needed is an assembler which preserves the relocatable versus absolute semantics of its input and marks those values in the output which need to be relocated so that the linker can identify them at link time. So the relocatable intermediate object code format plus the availability of an automatic linker and (hopefully) "librarian" utility, would COMPENSATE FOR the limitations of the 6502 instruction set and let us develop really decent language environments -- all ending up in the same relocatable format. If we could readily develop reusable software libraries, with the performance that languages like ACTION! and MAC65 give, we could greatly reduce the effort involved in developing high-performance application programs on the 8-bitters.

By the way, I understand that there is a recently-announced assembler that DOES produce relocatable object code, but unfortunately does not (yet) have macro capabilities. I can't locate the name and address I was given but will post it if I find it. Maybe their format will become the standard!

-John Sangster

P.S. Thanks to Sascha Segan for his reply about Turbo BASIC for the 800. Also, thanks to Fred Sullivan for his help with the ACTION! Block Read

question, and to the several others who also responded privately.

I wanted to share some of my thoughts on where the 8 vs 16 bit atari machines is going.

I have owned an atari 8 bit machine since 1980 and have loved every minute of it. I am now at a crossroads, however, in upgrading. As background, I have an 130XE, 810 drive, monitor, and an MX80 printer. Consider the following data (near best price from magazines):

413. Volksmodem 12

Newsgroup: comp.sys.atari.8bit
Date: 1987-05-06 15:55:00 UTC
From: IHLS400@INDYCMS.BITNET
Message-ID: <8705061809.AA26203@ucbvax.Berkeley.EDU>
Source record: 117667

Re: Volksmodem 12 and cables

I own a Volksmodem 12 and have had no problems with it whatsoever. I did have to call Anchor in California in order to order cables to attach through the 850 interface. They cost $14.95 (as opposed to $9.95 for standard Volks->IBM cables here in town) and were here within a week and a half. The only incompatibility I have found is with Chameleon not believing that it can dial the Volks when it actually has done that. It only means that Chameleon won't through itself into terminal mode automatically on connection. You have to escape to the main menu and then START into terminal mode. Most of the time I don't bother with the dialing menu anyway since I call numbers I know off the top of my head. I do wish it had a speaker, however.

Anchor also makes a modem for the 520ST at the same price (about $130) which does have a speaker. My best friend has it and has seemed to be very pleased with it.

Feel free to send any questions regarding the Volks to me directly. I will try to find the return path back through the network if I can.

414. Atari 20Meg for ST

Newsgroup: comp.sys.atari.8bit
Date: 1987-05-06 16:02:00 UTC
From: IHLS400@INDYCMS.BITNET
Message-ID: <8705061814.AA26341@ucbvax.Berkeley.EDU>
Source record: 117668

This may be more appropriate for Atari16, but when checking the cost of upgrading from 8 to 16 bit machines, don't overlook local stores in favor of mail order. Even with only two stores here that handle Atari, one was selling the SH204 for $575, the other for $600. (The higher priced store gives better service, I have always thought.) The same store is also carrying SF354 SS/DD drives for $99. You can't find those prices easily even mail order, and you don't get the technical assistance from most mail order places that you can get from walk-in. Certainly not all the prices are like this, but if you look or are in the position of being able to wait for a sale, you can find them.

Please feel free to contact me directly if you have any questions.

415. O.S.S. Bulletin Board

Newsgroup: comp.sys.atari.8bit
Date: 1987-05-06 17:26:36 UTC
From: benw@packard.UUCP
Message-ID: <568@packard.UUCP>
Source record: 117669

O.S.S, publishers of Action! and other Atari goodies, has recently started a public Bulletin Board. It contains files pertaining to all their products, and especially contains many Tips and utilities for and written in Action!. Their number is

1-408-446-3451

It's worth a call. By the way, it also includes the Action! bugsheets...I have'em, and will post them to the net if anyone wants them.

416. MPP-1000C/E Vs Turbo Basic and Rana disk drive

Newsgroup: comp.sys.atari.8bit
Date: 1987-05-06 18:21:00 UTC
From: Farkas@GODZILLA.SCH.SYMBOLICS.COM
Message-ID: <870506112156.2.FARKAS@KALI.SCH.Symbolics.COM>
Source record: 117670

I just got a copy of Turbo Basic and I love it!!!
I am having a problem using it with the MPP driver
program I got from Microbits. When I load the driver,
the appropriate message appears on the screen. I then
load Turbo Basic, which loads with no problem. Then,
whenever I try to access the modem, it either comes
back with a no such device error or it locks up.
Has anyone else had this problem and come up with
a solution? I called Supra and they said that Turbo
must be doing something wrong because that driver
was done "by the book".

Also, does anyone have any information (schematics,
service book, etc...) on the Rana 1000 disk drive?
I started having trouble with mine just after they
went belly up!
Thanks...

417. Re: 68000 vs. 6502, help with Turbo Basic

Newsgroup: comp.sys.atari.8bit
Date: 1987-05-06 21:12:03 UTC
From: 2FK8ALIN@UKANVAX.BITNET.UUCP
Message-ID: <8705062112.AA00312@ucbvax.Berkeley.EDU>
Source record: 117671

Date: Wed, 6 May 87 15:43 CST
From: <2FK8ALIN@UKANVAX.BITNET>
Subject: Re: 68000 vs. 6502, help with Turbo Basic
To: info-atari8@score.stanford.edu
X-Original-To: info-atari8@score.stanford.edu, 2FK8ALINE

Well, you do have a point about the 8.0 MHz 68000
being near 1.5 times as fast (in instructions per second
as a comparison) as a 1.8 MHz 6502. BUT...

The original point of the argument was that a 6502
might beat a 68000 at certain tasks given the above clock
speeds. Again, not true! As you yourself said, it would
be about 1.5 times faster given the data I supplied.
I need to clear up another point also. This stuff about
averages (in clock cycles) is too misleading. I have the
official MC68000 reference card in front of me at this
very moment, which includes all clock cycle data. Given
direct translation (as near as possible) from 6502 to
68000, there is not a single instruction quicker on the
6502 given the above clock speeds. For instance, look
at:

6502 inst. cycles 68000 inst. cycles 68000 speed inc
---------- ------ ----------- ------ --------------
INY 2 ADDQ.B #1, Dn 4 *2.23
JMP abso 3 JMP abso.W 10 *1.34
LDA abso 4 MOVE.W abso.W, Dn 12 *1.49

So, you say, 1.34 times is not very much. But as it turns
out, all instruction conversions turn out with the 68000
being faster at 8.0 MHz vs. those on a 1.8 MHz 6502.
By simple deduction, then, no task can be faster on a 6502, no
no matter how trivial or contrived. You can then take into
account the increased power of the addressing modes of
the 68000 (and, in fact, other instructions such as the
DIVS and MULS, divide signed and multiply signed) and
see how a "normal" program, such as a typical game or
assembler, would run much faster than 1.5 to 2 times that
of the 6502. Need I also mention the ability to
use 16 bit and 32 bit quantities with the processor?
Or maybe the 8 data registers AND 8 address registers?
Compare this to the 6502's 8 bit only quantities and its
three 8 bit data registers, which can't even be used in
uniform ways (INA does not exist, for instance).

By now it must appear that I am a lover of the 68000.
Believe it or not, this is not so! I only
defend the thing because it is FASTER than the 6502
and it lends itself to more powerful applications such
as multitasking/multiuser systems, relocatable coding, etc.
So, do I like the 6502 better? Yes, I think so. This
is because, I suspect, that I have programmed the little
thing since about 1981 (I got my Atari a little before then)
and the 68000 does have weaknesses. Some of these are:

I. Odd address errors. You cannot put words/longwords
on odd byte addresses or a processor trap occurs,
meaning program crash (and on the horrible Corvus
I have programmed, the system just dies without
any diagnostics!) It seems the designer thought
that 23 processor pins would do for 24 bit addressing.
8 bit quantities may be put on any address, however.

II. Bus access time slow. As I said before, it takes
4 cycles to access memory. It would be sooooo much
faster if it accessed every cycle as does the 6502.

III. LARGE instructions. The smallest instruction size
is 16 bits, the largest is 80 bits (gulp). The
6502 instruction sizes range from 8 to 24 bits.

I must admit that I really would love an ST
so I do have some divided loyalties, but I have had such
a time with my 800 over the years that I can't even think
of getting rid of it or giving up on it.

Concerning Turbo Basic for the 800:

I would really be interested in hearing more about this.
Unfortunately, I am just a Kansas University student and
my VAX account is about to die. I will be halting my
subscription to this newsletter until next year (I am a
CS major, so I will get one as soon as next year
begins). The point is: is anyone willing to send me
information, when found, on how to get it? My home
address is:

Eric Greene

419. languages and compilers

Newsgroup: comp.sys.atari.8bit
Date: 1987-05-07 02:39:00 UTC
From: SULLIVAN@suny-bing.CSNET
Message-ID: <8705070756.AA12474@ucbvax.Berkeley.EDU>
Source record: 117673

John Sangster asks why Action! compiles so quickly. I'm not sure there is
a simple answer, but I'll give it a shot.
1. Everything, including compiler and source, is typically in memory
rather than on disk. Also, the compiled code is loaded directly into
memory. The lack of disk access makes a HUGE speed difference. I don't
have a ramdisk, so I really notice this. Rumor has it that Ace C compiles
quickly with a ramdisk, but I haven't tried this.
2. Action! is a very minimal language. The following (and, of course, more)
don't exist in Action!
a. sophisticated data types, e.g. floating point numbers, multi-
dimensional arrays, files, arrays of records, arrays as fields of
records, recursively defined types, ...
b. recursion
c. strong type checking -- card can often be used interchangeably
with pointer types, for example
d. parameter passing by reference -- also true of C, of course
e. dynamic storage allocation -- ok, strictly speaking this is true
of C, but almost all C's (except those that run on Atari's) have
this available as an external procedure. sure, sure, I can write
one in Action.
f. good error messages. Although the language is so small, it is
usuall easy to find the syntax error
g. macros -- with parameters
h. conveniently usable functions -- the most annoying thing about
Action! to me (if anyone from OSS reads this - take note - I really
really really hate this) is that function values cannot be used in
expressions.
Of course, all of the above except b. and h. also apply to the C's which
are available on Atari machines. In addition, the C compilers don't produce
6502 code. They produce a sort of P-code which is interpreted at run-time.
Thus execution speeds suffer.
3. OSS, or whoever wrote it, did a good job. I have my gripes, but
compared to other languages available, I can't complain too much. On the
other hand, I still regard Action! as a "toy language". I would hate to
have to produce software professionally using this compiler, or any other
on Atari machines. The mental comparison I keep making is with Turbo Pascal.
Note -- I am not an IBM PC advocate. I only touch them when I'm forced to.
Turbo Pascal is similar to Action! in speed, convenience (built-in editor, etc),and size of
machine (it runs in 64K) but it is a full Pascal implementation.

A query - (I've asked before, but no-one answered):
How is Kyan Pascal. How fast? How many bugs? Is it a full implementation?

423. Kayan Pascal

Newsgroup: comp.sys.atari.8bit
Date: 1987-05-08 00:12:42 UTC
From: 2FKKAPSE@UKANVAX.BITNET
Message-ID: <8705080019.AA28750@ucbvax.Berkeley.EDU>
Source record: 117677

Date: Thu, 7 May 87 19:11 CST
From: <2FKKAPSE@UKANVAX.BITNET>
Subject: Kayan Pascal
To: info-atari8@score.stanford.edu
X-Original-To: info-atari8@score.stanford.edu, 2FKKAPSE

As a parting remark in his comments about ACTION!, Fred Sullivan
asked how good Kayan Pascal is.

I have been using Kayan now since before Christmas and it works
fairly well. It is a full implementation of the ISO standard.

Beware, however. Kayan Pascal produces HUGE code. Typical of
most non-optimized code written by pascal compilers, the
Kayan code appears upon disassembly to be filled wtih run-time
error checking, which some consider a useless distraction.
Needless to say, the finished product will be SLOW.

Kayan's best feature is the ability to stick assembly routines
directly in the code. This appears to be the best way around
the run-time error checking.

If you want optimal compiled code, stick with ACTION! (or assembly.)
If you want the best (in my opinion) implementation of ISO pascal
available for the 8-bits and are really not concerned wtih how big your
object files get, Kayan is definitley worth it.

One final comment: The combination of Kayan Pascal and a good code
optimizer would make a terrific programming tool. Hint, hint:
has anybody beaten me to it, or do I have to do all the work myself?

I have been told that the Atari 400 is incapable of supporting a 1200 baud modem. Anyone know if this is true or not. I don't see why it wouldn't.

Does anyone know what the pin configuration for a standard RS-232 25 pin connector is? I.e. pin 4 data send etc.

Finally, I see adverts all the time from Radio Shack for replacement keyboards, however I have yet to see one that they make that will connect to my 400. Can you alter the output pins from the keyboard to match the Atari? Is there a full stroke keyboard around that will connect to the 400? (Other than the b-key).

Dave

Source record: 117680

Thanks to Eric Greene for his more careful comparison of 6502 and 68000 instruction timing. I bow to his greater knowledge of the 68000 (and probably the 6502 also) and agree that his data proves that the best a 6502 could hope to do is come within 1/1.34 or about 74% of the speed of a 68000 with the respective clock speeds used in the 800XL and the ST (1.76 MHz and 8 MHz respectively). Had I noticed that there are 68000 instructions that execute in only 4 clock cycles, and looked as closely as Eric has at which instructions are that quick, I would not have suggested that the 6502 might win on some benchmarks. I hope the exercise in comparing the two processors has been enlightening to others as well as to me.

Of course, we still have the ANTIC and POKEY to contend with in the 8-bit Ataris. I won't contest the fact that the ST is a more powerful machine overall, but I will expect the 8-bitters to continue to hold their own in animated graphics and sound generation, at least until the much-awaited Blitter (and maybe a sound chip with more voices) arrives in the ST line. Considering the price difference and the age of the 8-bit technology, Atari deserves great credit for the performance they got from the 8-bit architecture, lo those many years ago!

-John Sangster / jhs@mitre-bedford.arpa

427. ACTION! BugSheets 1-6 (Complete Set)

Newsgroup: comp.sys.atari.8bit

================================================================================

ACTION! BUG SHEET #3 - part 1

This document supercedes the previous
two bug sheets published for ACTION!

November 6, 1984

-----------------------------------

GENERAL INFORMATION

Before getting to the bad stuff (the
bugs), here are some goodies about
ACTION! which we would like to pass
on to you:

TIPS ON TEMPS

A magazine article titled "Lights,
Camera, Action!" (by Dave Plotkin)
which appeared in the July 1984 issue
of ANTIC featured a set of routines
to facilitate writing ACTION!-based
interrupt handlers.

The article gave the listings for two
routines (more properly, two DEFINEs)
named "SaveTemps" and "GetTemps".
These routines are adequate only if
```

no math beyond addition and
subtraction is performed in the
interrupt service routine. The
following versions of these two
routines will work properly in the
more general case:

Make the following DEFINEs in your
program before you declare your
interrupt routine (comments may be
omitted-- they exist only for clari-
fication):

```
DEFINE SaveTemps=
"[
$A2 $07 ; LDX #7
$B5 $C0 ; LOOP LDA $C0,X
$48 ; PHA
$B5 $A0 ; LDA $A0,X
$48 ; PHA
$B5 $80 ; LDA $80,X
$48 ; PHA
$B5 $A8 ; LDA $A8,X
$48 ; PHA
$CA ; DEX
$10 $F1 ; BPL LOOP
$A5 $D3 ; LDA $D3
$48 ; PHA
]"

DEFINE GetTemps=
"[
$68 ; PLA
$85 $D3 ; STA $D3
$A2 $00 ; LDX #0
$68 ; LOOP PLA
$95 $A8 ; STA $A8,X
$68 ; PLA
$95 $80 ; STA $80,X
$68 ; PLA
$95 $A0 ; STA $A0,X
$68 ; PLA
$95 $C0 ; STA $C0,X
$E8 ; INX
$E0 $08 ; CPX #8
$D0 $EF ; BNE LOOP
]"
```

Use these routines inside your
interrupt routine as follows:

```
; Your interrupt routine.
PROC InterruptRoutine()
; Local declarations, if any.
BYTE a, b, c, etc.

; First line of code within
; procedure
SaveTemps

... ; Your interrupt
; code goes here.

GetTemps ; Last line of code
; within procedure.
[$6C OldVBI] ; A special way to
; end for VBIs- see
; below.
```

For example, the following program will set up the routine ChangeColor as a vertical blank interrupt routine (hit the START key to exit the program):

```
DEFINE SaveTemps=
"[ $A2 $07 $B5 $C0 $48
$B5 $A0 $48 $B5 $80
$48 $B5 $A8 $48 $CA
$10 $F1 $A5 $D3 $48 ]"

DEFINE GetTemps=
"[ $68 $85 $D3 $A2 $00 $68
$95 $A8 $68 $95 $80 $68
$95 $A0 $68 $95 $C0 $E8
$E0 $08 $D0 $EF ]"

CARD OldVBI ; Will hold previous
; contents of vertical
; blank interrupt
; vector.

; This procedure will change the
; background color to random values.
; The main routine will set up this
; code to operate during the
; deferred vertical blank interrupt.
PROC ChangeColor()
BYTE hue, lum

SaveTemps
hue = Rand( 16 )
lum = Rand( 16 )
SetColor(2,hue,lum)
GetTemps
```

```
[ $6C OldVBI ] ; Vertical blank
; interrupts must end
; like this ($6C is a
; 6502 indirect jump
; instruction).

PROC Test() ; Main routine
BYTE critic=$42, ; Critical I/O flag
console=$D01F ; Console key
; hardware location
CARD VBIvec=$224 ; Deferred vertical
; blank interrupt vector

; You must install a VBI
; routine like this:
critic = 1
OldVBI = VBIvec
VBIvec = ChangeColor
critic = 0

; ChangeColor is now running
; as the vertical blank interrupt
; routine-- since our mainline
; code has nothing more to do,
; we just go into a loop waiting
; for the START key to be
; pressed.
WHILE consoleVISITOR DO
OD

; Now turn off the VBI routine.
critic = 1
VBIvec = OldVBI
critic = 0
RETURN

This method of saving and restoring
ACTION zero page variables may also
be used to write BASIC machine
language subroutines in ACTION! Your
main ACTION routine should then have
SaveTemps as the first executable
line, and GetTemps as the last
executable line before the RETURN
statement.
--------------------------------------------------------------------------
ACTION! BUG SHEET #3 - part 2

-------------------------------------

BUGS IN THE ACTION! CARTRIDGES
```

The following is a list of all bugs we currently know exist in the ACTION! cartridge. We list these bugs separately from those in the RunTime library and/or the PAD disk or ToolKit, which occur in following pages. Each bug is described in detail and, when possible, bug fixes are given. Many of these bugs deal only with specific versions of ACTION!. To find out which version of ACTION! you own, type the following from the ACTION! monitor:

?$B000 [RETURN]

Below is an actual copy of what printed following that command for one of our cartridges.

```
45055,$B000 = 0 $0730 48 1840
^
```

To find out the version number, look at the character to the right of the equals sign (here printed with a caret under it). The "0" in this case implies that the cartridge is version 3.0. If yours has a "6", you own version 3.6, etc. As of the date of this bug sheet, the current cartridge version is 3.6.

1. OFFSETS -- Using a TYPE declaration will generate a spurious error whenever the code offset (contents of location $B5) is non-zero.

Affects: All versions of the cartridge to date. (Presumably only noticed if using RunTime disk, though.)

Fix: Make all TYPE declarations before changing the code offset.

Example:

```
; Beginning of program --
; First, declare TYPEs
TYPE IOCB =
[
BYTE Id, Devnum,
Command, Status
```

```
]

; Then, if desired,
; change offset
SET $B5 = $1000
; example: offset=4096
```

2. OFFSETS -- Using a code offset greater than $7FFF (i.e., a negative offset, if you consider it to be of type INT) causes the compiler to generate improper code.

Affects: All versions, especially when used with the RunTime disk.

Fix: No direct fix, but you may use the relocator program described later in this document (which is also usable with assembly language).

3. ATARI DOS -- Exiting to Atari DOS from ACTION! can cause a system crash if DUP.SYS is not present on the disk in drive 1.

Affects: All versions, but only when used with Atari DOS.

Fix: Use DOS XL (or be careful when exiting to DOS).

4. ARRAYS AND ELSEIF -- We have just learned that there is a relatively obscure bug in ACTION! related to the use of ELSEIF. In particular, statements similar to the form
ELSEIF a(i) = 0 THEN ...
(where a is an ARRAY and i is a CARD OR INT), or statements like
ELSEIF p^ = 0 THEN
(where p is a POINTER) produce incorrect code.

Affects: All versions

Fix: There is no direct fix at this time. The best way around the problem seems to be to code

something like this:
t = a(i) ; t is an INTEGER
...
ELSEIF t=0 THEN ...
This works properly.

5. WRITING OBJECT FILES -- If a monitor Write command fails because of a disk error (e.g., disk full, 162, or device done, 144), the IOCB is not properly closed. If the disk is changed before another disk operation is performed, the new disk can have invalid data written to it.

Affects: All versions

Fix: If you get an error when writing an ACTION! object file, type the following command to the monitor:
X Close(1) [RETURN]
You can then erase the file which caused the error.

6. HEX ARRAY SIZES -- Hexadecimal values as array dimensions cause incorrect code to be generated.

Affects: All versions

Fix: Use decimal array dimensions.

7. TYPE POINTER ARGUMENTS -- PROC/FUNC declarations with record pointer arguments other than the first don't compile correctly. For example, the following code generates an error 7 (invalid argument list):
TYPE REC=[...]
...
PROC Test(BYTE x, REC POINTER p)

Affects: All versions

Fix: Omit the comma in the argument list for the PROC/FUNC, as in:
PROC Test(BYTE x

```
REC POINTER p )
```

As this is just a temporary fix, it may not work in future versions, but the correct declaration (with the comma) will.

8. MONITOR LOCKUP -- Typing the following command from the monitor will lock up the system:
R* [RETURN]

Affects: All versions

Fix: Don't do it! If you do type that command, hit [RESET]

9. PADDLE FUNCTION -- The Paddle function does not work properly in all versions of the ACTION! cartridge.

Affects: Versions 3.0 to 3.5

Fix: Make the following declaration in your program:
BYTE ARRAY Paddle(4) = 624

10. SOUND ON CHANNELS 3 AND 4 -- If you use a Sound() procedure call after having done any disk I/O, sound channels 3 and 4 will remain silent. This is because Atari's OS does not reset some of the serial control registers completely.

Affects: Versions 3.0 to 3.5

Fix: Type in and use the following procedure. You should call this before doing any Sound() calls and/or in place of any SndRst() calls:

```
; Contributed by Michael Ross
PROC SoundOff()
BYTE AudCtl = $D208,
SSKCtl = $232,
SKCtl = $D20F

SSKCtl = 3
SKCtl = 3
```

```
AudCtl = 0
SndRst()
RETURN
```

11. TYPE FIELDS AS PARAMETERS -- Using fields of TYPEs as parameters to PROCs or FUNCs generates incorrect code. For example,

```
MoveBlock( rec.addr1,
rec.addr2, length )
```

Affects: Versions 3.0 to 3.5

Fix: Assign the TYPE field to a temporary variable and pass that as a parameter:

```
temp1 = rec.addr1
temp2 = rec.addr2
MoveBlock(temp1,temp2,length)
```

12. SASSIGN PROBLEMS -- SAssign does not work properly when the source string has a length of zero.

Affects: Versions 3.0 to 3.5

Fix: No fix available at this time.

13. CARD FIELDS IN TYPES -- Accessing CARD fields of TYPEs generates incorrect code.

Affects: Versions 3.0 to 3.2

Fix: No fix available at this time.

14. MOVEBLOCK PROBLEMS -- MoveBlock does not move more than 256 bytes of data.

Affects: Versions 3.0 to 3.2

Fix: No fix at this time. You could write an ACTION! routine to do the equivalent.

15. CONTROL-SHIFT RETURN -- Using [CS] RETURN to split a line into two lines generates garbage in the second line.

Affects: Versions 3.0 and 3.1

Fix: No fix available, but not a disastrous problem.

16. DIVISION ERRORS -- On old cartridges, neither the "/" operator nor the "MOD" operator works properly under certain conditions.

Affects: Versions 3.0 and 3.1

Fix: Insert the following code into your program before any of your own PROCedure or FUNCtion declarations (this can be done easily using INCLUDE):

```
; Copyright (c) 1983 by
; Action Computer Services
;
; Permission is granted to
; duplicate and/or distribute
; the contents of this file
; to ACTION! users. Copies of
; this file may not be sold or
; used for monetary gain.

PROC DivI=*()
[$20 $A06C $85 $86 $A2 $10
$26 $82 $26 $83 $26 $86 $26
$87 $38 $A5 $86 $E5 $84 $A8
$A5 $87 $E5 $85 $90 $04 $85
$87 $84 $86 $CA $D0 $E5 $A5
$82 $2A $26 $83 $A6 $83
$4C $A032]

PROC RemI=*()
[$20 DivI $86A5 $87A6 $60]

SET $4EA=DivI
SET $4EC=RemI
```

17. ERROR ROUTINE NOT INITIALIZED -- The address of the Error PROCedure is not restored by ACTION! if a user program has changed it.

Affects: Versions 3.0 and 3.1

Fix: Make sure to restore the original Error vector upon exiting a program, if you changed it.

18. COMPLEX EXPRESSIONS IN UNTIL --
Complex relational expressions in
an UNTIL statement generate
incorrect code. For example,

```
DO
...
UNTIL a>0 AND b=3
OD
```

Affects: Versions 3.0 and 3.1

Fix: Assign the expression to a
temporary variable and test that
variable, instead:

```
DO
...
temp = a>0 AND b=3
UNTIL temp
OD
```

19. BANK SWITCH BUG -- When loading
and running compiled ACTION!
object files from DOS, the system
can crash when using older
cartridges. This is because the
ACTION! library is not
accessible.

Affects: Version 3.0 only

Fix: Put the following program
lines at the VERY BEGINNING of
your main procedure (i.e., the
last procedure in your program):

```
BYTE bank = $D500
; This declares the variable
; 'bank' to reside at $D500.

bank = 0 ; This must be the
; first executable statement.
```

20. .COM PROGRAMS -- Running compiled
ACTION! programs as .COM files
under OS/A+ causes those programs
to execute twice.

Affects: All versions, but only
when using a version of OS/A+.
DOS XL is not affected.

Fix: Insert the following as the
first global variable you
declare:

```
BYTE RTS=[$60]
; This MUST be the first
; line in your program,
; aside from comments and
; SET commands.
```

21. PROC ADDRESSING -- Under certain conditions, specifying the address of a procedure (e.g., to interface to a machine code routine) causes ACTION! to generate incorrect code which could cause your program to "hang".

Affects: Versions 3.1 and 3.4

Fix: Insert an empty code block after the declaration of a procedure whose address is specified. For example:

```
PROC CIO = $E456() []
; An empty code block!
```

22. ERROR #3 -- If you get an ERROR 3 during a compile, the system hangs when you return to the editor.

Affects: All versions

Fix: Do not go to the editor until you type the following line to the monitor. This command resets the ACTION! memory pointer.

```
SET $E=$491^
```

23. STRING INPUT -- When using the string input library functions (InputS, InputSD, and InputMD), there must be room in the string for the termination EOL, even though the resulting string length will not include it.

Affects: All versions

Fix: Adjust your declaration appropriately.

ACTION! BUG SHEET #3 - part 3

```
-------------------------------------

BUGS IN THE ACTION! RUNTIME LIBRARY

We have found a few bugs in the
original version(s) of the RunTime
Library Disk. Fortunately, they are
all easy to fix. (The RunTime
library is independent of the
cartridge, so bugs affect all
versions.)

In the fixes given below, the portion
to be changed (to implement the fix)
is underlined. The rest of the line
remains the same. To make the fixes,
simply load the library file
containing the affected PROCedure,
edit, and save it back to disk.

1. Hex numbers are printed
incorrectly by PrintH and the %H
parameter of PrintF.

Fix: Change second line of CCIO:

PROC CCIO=*()
[$A386$A0A$A0A$AA$A3A5$9D$342 ...
--- ---

2. PrintBDE can cause a spurious
compile time error.

Fix: Change first line of
PrintBDE:

PROC PrintBDE =*(BYTE d,n)[$A0$0]
--
3. A minor error exists in ChkErr.

Fix: Change second line of
ChkErr:

PROC ChkErr=*(BYTE r,b,eC)
[$1610$88C0$8F0
$98$80C0$12F0 ...
---
4. If your program redefines a
library procedure (e.g., one
which declares its own version of
PROC Graphics), it will compile
with no errors using the
cartridge only (because declared
procedures take precedence over
built-in ones). However, since
```

the RunTime library uses this
same precedence trick to include
its own definitions of library
procedures, your program will
generate Error 6 (doubly defined
name) if you do not delete the
appropriate PROCedure (or
FUNCtion) from the RunTime
library before INCLUDEing it.

Fix: Make a custom version of
the RunTime library on a COPY
(please, only on a copy) of your
RunTime disk which does not
contain the routines you wish to
replace.

5. On page 17 of the Reference Guide
for the Runtime Package, the
DEFINE for ROM will cause
incorrect code if you use local
variables.

Fix: Use the following form of
definition, instead:

```
DEFINE ROM = "BYTE ZZQQJUNK
-------------
SET $680 = $E^
SET $B5 = $5800
SET $E = $682^"
```

ACTION! BUG SHEET #3 - part 4

PROBLEMS WITH PAD

We will list the problems (and
solutions) regarding the Programmer's
Aid Disk here in reasonably compact
form.

1. BGET/BPUT PROBLEMS -- The BGet
and BPut routines in the IO.ACT
file do not work properly under
certain conditions. To fix this
bug, replace the BGet and BPut
routines with the following
ACTION! code:

```
;*******************************
;Burst (Block) I/O routines to do
;quick disk I/O, utilizing a call
; to CIO
;*******************************

PROC CIO=$E456( BYTE areg, xreg )

;*******************************

CARD FUNC Burst( BYTE chan, mode,
CARD addr, buflen )

TYPE IOCB=[BYTE id,num,cmd,stat
CARD badr,padr,blen
BYTE a1,a2,a3,
a4,a5,a6]

IOCB POINTER iptr

chan ==07
iptr = $340+(chan LSH 4)
iptr.cmd = mode
iptr.blen = buflen
iptr.badr = addr
CIO( 0, chan LSH 4 )
RETURN( iptr.blen )

;*******************************

CARD FUNC BGet( BYTE chan,
CARD addr, len )
CARD temp

temp = Burst(chan,7,addr,len)
RETURN( temp )

;*******************************

PROC BPut(BYTE chan,
CARD addr,len)
Burst( chan, 11, addr, len )
RETURN
```

2. PRINTF -- The PRINTF routine has a bug which was reported and fixed in the Spring, 1984 newsletter. In the file PRINTF.ACT, use the ACTION! editor to find

```
args ==+ s
```

and change it to

```
args ==+ 2
```

3. PLAYER/MISSILE GRAPHICS --
Because S: uses some memory just
below the display list
(undocumented), our method of
finding the base address for
Player/Missile Graphics needs a
slight revision. Use the ACTION!
editor with the file PMG.ACT to
find
PM_BaseAdr=(HiMem-
PM_MemSize(mode))
_AdrMask(mode)
and change it to
PM_BaseAdr=(HiMem-
PM_MemSize(mode)-$80)
_AdrMask(mode)

4. If you use the PMMove procedure
and specify a vertical movement
of zero, the horizontal movement
does not take place (it should).
To fix this, change the lines in
PMG.ACT which read
IF deltay=0 THEN
RETURN ; do nothing
FI
to the following:
IF deltay=0 THEN
; do horizontal anyway
PMHpos(n)=x
RETURN
FI

5. PLAYER/MISSILE GRAPHICS -- The
documentation for PMG.ACT states
that you may read the contents of
PMHpos to find the horizontal
position of a player or missile.
This is simply not true. PMHpos
is a set of write-only hardware
registers. (Note that in the
ToolKit we have added a shadow
array and changed the name of the
hardware registers, so this works
correctly. If you wish, you
could consider doing something
similar on your PAD.)

6. REAL NUMBER ROUTINES -- There are
two discrepancies in PROCedure
names in the REAL.ACT library as
compared to the REAL.DOC

documentation, as follow:
Name in .DOC Name in .ACT
StrR RealToStr
ValR StrToReal
We suggest that you change the
source code in REAL.ACT to
reflect the names given in the
documentation (rather than vice
versa), since this makes the
names appear compatibile with the
library's other number-string
conversion routines.

7. REAL NUMBER ROUTINES -- In that
same area, the routine RealToStr
(or should that be StrR?) needs
to change the line which reads
ptr=LBuff
to the following:
ptr=InBuff

8. ALLOC.ACT -- The free list
pointer may not be set up
properly. Also, when freeing a
block, right adjacency is not
handled properly if left
adjacency has already been found.
Fix these problems as follows:

In the PROCedure Free, after the
line reading:
last.size==+nBytes
insert the line:
target=last

Also, in the same procedure,
change the line reading:
IF target+nBytes=current THEN
to read:
IF target+target.size
=current THEN

In the PROCedure AllocInit,
replace the line reading:
FreeList.next=p
with the following lines:
FreeList=p
p==+4
FreeList.next=p

TOOLKIT TROUBLES

It's hard to believe that a product as new as the ACTION! ToolKit can already have bug reports. Sigh. Anyway, there are already three versions of the ToolKit. Version 1 has 31 free sectors (when you list its directory). Version 2 has fewer free sectors and the second line of the file MUSIC.DEM reads ";Version 2". On version 3, the file ABS.ACT starts with the version number. This last convention will be followed in future versions. The comments here are organized by affected version(s).

VERSION 1 ONLY

1. I/O ROUTINES -- The manual describes a routine called Format (in the IO.ACT library), but no such procedure exists on the disk. However, the routine is there--it's just called Init instead. You should change your disk to match your manual.

2. MUSIC.DEM -- The program called MUSIC.DEM will not work as is on older 400/800 machines. This is because it uses a call to Graphics(15), which is only available on XL machines. You may change the program to use Graphics(8) with no effect except that the true colors of mode 15 become artifact colors in mode 8 instead.

VERSIONS 1 AND 2

1. REAL ROUTINES -- There are two discrepancies in PROCedure names in the REAL.ACT library as compared to the REAL.DOC documentation, as follow:

Name in .DOC Name in .ACT
StrR RealToStr
ValR StrToReal

We suggest that you change the source code in REAL.ACT to

reflect the names given in the documentation (rather than vice versa), since this makes the names appear compatibile with the library's other number-string conversion routines.

2. SORT ROUTINES -- There are four discrepancies in PROCecure names in the SORT.ACT library as compared to the SORT.ACT documentation, as follows:

Name in .DOC Name in .ACT
SortB BSort
SortC CSort
SortI ISort
SortS SSort

Please change your disk file to agree with your manual.

3. PRINTF -- The PRINTF routine has a bug which was reported and fixed in the Sprint, 1984 newsletter. In the file PRINTF.ACT, use the ACTION! editor to find
args ==+ s
and change it to
args ==+ 2

VERSIONS 1, 2, AND 3.

1. ALLOC ROUTINES -- The manual indicates that the procedure AllocInit requires that you pass it the address of the first free byte of memory (because Alloc "dispenses" memory from the first free byte through the top of memory, as correctly described in the manual). However, since you MUST follow the procedure described in the introduction to ALLOCATE.ACT (that is, you must declare in your program a CARD called EndProg and use the command
SET EndProg=*
after compiling), the parameter to AllocInit is not really needed

and so has been eliminated.
(AllocInit uses EndProg just as
Alloc does.) If you pass a
parameter to AllocInit, it will
be ignored.

2. WARP.DEM -- No mention is made in
the Toolkit manual that this file
can only be run when compiled
from disk (unless you are using
DOS XL to gain extra memory).
WARP.DEM is just too big for
ACTION! to hold both the source
and object in memory at one time.

3. ALLOCATE.ACT -- The free list
pointer may not be set up
properly. Also, when freeing a
block, right adjacency is not
handled properly if left
adjacency has already been found.
Fix these problems as follows:

In the PROCedure Free, after the
line reading:
last.size==+nBytes
insert the line:
target=last

Also, in the same procedure,
change the line reading:
IF target+nBytes=current THEN
to read:
IF target+target.size
=current THEN

In the PROCedure AllocInit,
replace the line reading:
p=EndProg
with the following lines:
FreeList=EndProg
p=EndProg+4

ACTION! BUG SHEET #3 - part 5

ACTION MANUAL ERRATA

First of all, you need to know which
version of the manual you have. If
Part III is the Language, then you

have the first version of the manual.
Otherwise, you have the second
(newest) version. Unfortunately,
both manuals contain content as well
as typographical errors. We'll skip
the typos and concentrate on the
content errors, since typos don't
impair your understanding of the
language (although you may wonder
where we learned to spell).

VERSION 1 ERRATA:

PAGE ERROR
2 In the last paragraph, it says
that the library is on the
disk. This is not true. It's
in your cartridge.

23 Under the description of
<BACK-S>, the comparison with
the Atari screen editor is
exactly reversed. If you are
in REPLACE mode, this key
works as in the Atari editor.

26 Under <CTRL><SHIFT>T, it says
you may not use lower-case
characters as tags. This is
untrue.

48 In the NOTE preceeding 4.3,
you should add "The *, /, and
MOD operators result in an
implied INT type. For this
reason, multiplication,
division, and modulus of large
CARD numbers does not always
work properly."

49 Section 4.4 says that you may
only have one special operator
in a complex relational
expression. This is untrue.
For example, the following is
perfectly legal:

(x=7 AND y#10) OR z<100

82 Section 6.2.3 implies that you
may not use a function as a
procedure. This is not true.
You may call a function as

though it were a procedure,
but the value returned from
the function is ignored.

97 Section 8.1.1 states that you
may either initialize a
POINTER to an address or give
it a value. Only the second
is possible, and you should
use this form:

BYTE POINTER x=<value>

Not this:
BYTE POINTER x=[<value>]

99 In example #1 there are two
PrintF statements which have
"ptr" as one parameter. These
should be "bptr", not "ptr".

101 In the last example of ARRAY
declaration (BYTE ARRAY
tests(5)...), the dimension is
overruled by the
initialization options, and so
its dimension is only three.
To fill only the first 3 of 5
elements, do the following:

BYTE ARRAY tests(5)=
[4 7 18 0 0]

104 In example #3 you see the
program line "PrintE(b)".
This should read
"PrintE(barray)".

108 Section 8.3.1.2 states that
you can initialize the fields
of a record when you declare
it. This is untrue; you may
only initialize its address.

110 The program line "rec.level =
InputB()" should read
"rec.level = GetD(7)".

112 Same as previous error.

115 Same as previous error.

112 The program line
"continue=InputB()" should

read "continue=GetD(7)"

120 The program line
"mode=InputB()" should read
"mode=GetD(7)", and the
program line "PrintE(name)"
should read "PrintE(nameptr)".

115 Same as previous error.

122 The program line
"incctr=chgclr" should read
"incclr=chgclr".

142 Section 5.3 states that you
should not use channel 7.
ACTION! uses this channel to
get characters from the
keyboard, and you may use it
to do this also. However,
don't close this channel or
alter its configuration in any
way.

153 The example of declaring an
ACTION! procedure at an
address is wrong! If you do
this, the internal pointer to
the procedure will point to
the specified address, but the
code generated by the
procedure will not be there.
Instead, it will be in with
your main code. Use procedure
and function addressing ONLY
to call machine language
routines.

161 Where the table of contents
lists the routines in section
2.3, it should read:

PrintBD NOT PrintDB
PrintCD NOT PrintDC
PrintID NOT PrintDI

162 Where the table of contents
lists the routines in sections
6.7 and 6.8, it should read:

PeekC NOT CPeek
PokeC NOT CPoke

165 Error in section 2.3. See changes for pg. 161 and make similar corrections.

179 Section 6.4 states some information concerning the results of misusing the SCopy routine, detailing that the routine does string trucation, etc., to make the procedure work. This is not true. You must make sure that the strings are compatible in size.

181 Section 6.8 states that the parameters to Poke and PokeC consist only of an address. Instead, they consist of an address and a value, as follows:

Poke(<address>,<BYTE value>)
PokeC(<address>,<CARD value>)

182 Section 6.11. MoveBlock will move a maximum block of 256 bytes in versions 3.0 to 3.4 of ACTION! Versions 3.5 and up will move any number of bytes.

191 Some error numbers are wrong. The corrections are:

14 Out of Space
15 Missing DO
19 Missing OD
24 Illegal FOR statement
26 Nesting Too Deep
27 Illegal TYPE reference
28 Illegal RETURN
128 BREAK key abort

Also, error 62 is error 61, and 54 NONE6 do not exist.

197 In the PrintF statement, %D should be changed to %U.

VERSION 2 ERRATA:

PAGE ERROR
38 Section 2.7, paragraph 3. The

last sentence states that you can RUN compiled ACTION! programs from disk. This is untrue. The RUN command will only compile and run ACTION! source files. Use DOS to run compiled object files.

39 The last RUN example (RUN PrintE()) will not work, since RUN expects a file name. Use the "Xecute" command instead.

63 In the TECHNICAL NOTE preceeding section 4.3, "*" should be changed to "*, /, or MOD".

126 The last assignment on the page makes newrecord point to the current record in the array, not the end of the array.

132 The program line "mode=InputB()" should be changed to "mode=GetD(7)".

138 The program line "IF sub(1)=str(ctr)" should read "IF sub(1)=str(ctrl)".

163 The PutDE procedure requires only a channel as a parameter, and does not put out both a character and a <RETURN>. Rather, it puts out a <RETURN> only.

172 In graphics mode 0 and all text windows, color 1 is the character luminance, color 2 is the background color, and color 3 is unused.

174 In section 5.6, references to the "lower right corner" should instead be "lower left corner".

180 Section 6.1.2 states some information concerning the results of misusing the SCopy

routine, detailing that the
routine does string
truncating, etc. This is not
true. You must make sure that
the strings are compatible in
size.

182 Section 6.11. MoveBlock will
move a maximum block of 256
bytes in versions 3.0 to 3.4
of ACTION! Versions 3.5 and
up will move any number of
bytes.

ACTION! BUG SHEET #3 - part 6

ACTION OBJECT CODE RELOCATION PROGRAM

The program SIMPLREL.ACT on this BBS
may be used to cause an ACTION!
program to load and run at a
different address than that address
at which it was compiled. The same
program will also work for assembly
language object files, providing you
also follow the given instructions.

The program takes two object files as
input and produces a third file which
will load and run at a desired
address. The relocating program
prompts the user for the two input
files, which must have been compiled
one page (256 bytes) apart. It then
prompts for an output file name (the
relocated file), the page number of
the starting address of the first
file, and the page number of the
desired destination address. Both
page numbers must be decimal values.
For example, specifying 32 as the
destination page will cause the
output file to load at address 32*256
($2000), not $3200.

See part V, "The ACTION! Compiler",
chapter 2, page 144, for information
on compiling programs to a specified
address (Used to compile the two

object files one page apart).

In order to use the relocating
program, download SIMPLEREL.ACT and
read the instructions therein.

==========

Fix for PrintF on Action! Toolkit

The PrintF routine on the Action!
Toolkit works great unless you try to
print a CARD value greater than
32767, or try to print the INT value
-32768. The reason these problems
occur is that the PROC PF_NBase in
the PRINTF.ACT file uses the "/" and
"MOD" operators, which call the
cartridge divide routine. The divide
routine is a SIGNED divide, so it
doesn't work for large card values.
The solution is to insert an UNSIGED
divide routine into the PRINTF.ACT
file and use it, instead. First,
insert the following code at the
beginning of PRINTF.ACT:

```
CARD Quotient, Remainder

PROC UDiv( CARD a, divisor )
DEFINE GETCARRY="[$2E carry]"
BYTE carry, i
CARD temp

Remainder = 0
FOR i = 1 TO 16
DO
Remainder ==LSH 1
Quotient ==LSH 1
IF (a000)#0 THEN
Remainder ==% 1
FI
a ==LSH 1
temp = Remainder - divisor
GETCARRY
IF (carryVISITOR#0 THEN
Remainder = temp
Quotient ==+ 1
FI
OD
RETURN
```

Some code in the PROCedure PF_NBase
must also be changed. Find the
section of code that reads as
follows:

```
WHILE n>0
DO
d=n MOD base <-
IF d<10 THEN
d==+'0
ELSE
d==+55
FI
s(ptr)=d
ptr==-1
length==+1
n=n/base <-
OD
```

And change the two lines indicated so
the code reads like this:

```
WHILE n>0
DO
UDiv( n, base ) <-
d=Remainder <-
IF d<10 THEN
d==+'0
ELSE
d==+55
FI
s(ptr)=d
ptr==-1
length==+1
n=Quotient <-
OD
```

The resulting PrintF routine will
work properly for all CARD and
INTeger numbers.

428. Chameleon vs Volksmodem

Chameleon will work with a generic Hayes compatible modem and the 850. What it
will do with a Volksmodem, I am not certain. However, you must adjust several
of the settings depending upon what your mainframe wants. I.e. parity,
xon/xoff, and various other settings. If you do not, then Chameleon will do
strange and wonderful things. Also, I have found that the termcap for the
vt52XL seems to work the best. Lots of luck!

>(Other than the b-key).

In general, no. I purchased one of the Radio Shack Keyboards once-- when they had ADAM remnants. The reason you can't do it easily is that all keyboards, in general, are matrixed differently. Computers send a certain number of lines out to their keyboards, and require a certain number of lines of responses. These lines vary from computer to computer. For example, an Atari Keyboard might sense a letter "J" when it sends out on it's first line and receives a signal on its first input line. Another Keyboard might put "J" somewhere else entirely. Furthermore, even writing a translator program is difficult, because different keyboards have different numbers of input and output lines.

Does this mean you're stuck? Of course not. There are lots of mail order places that you can order real Atari keyboards from. I'm sure the other people on the net who know what these places are would be happy to tell you.

Good luck!

430. A C Compiler

Newsgroup: comp.sys.atari.8bit
Date: 1987-05-08 19:40:57 UTC
From: smk@cbosgd.ATT.COM
Message-ID: <3592@cbosgd.ATT.COM>
Source record: 117684

I am currently putting the finishing touches on a custom version of
Deep Blue C (DBC). New features currently supported are:

1. aggregate types: structs, unions, and arrays (including multi-
dimensional arrays). (No fields, sorry!)

2. combinations of types, i.e., "pointer to pointer to function
returning pointer to ..."

a. functions may return int, char, and pointers to anything

b. indirect function calls properly supported, i.e., "(*pfunc)()"

3. sizeof and type cast operators.

4. . and -> operators.

5. goto statement.

6. "static" declarations.

7. #define "functions", #ifdef, #else, and #endif.

8. Compiles a little bit more than 2.5 times faster than DBC. Even
faster if program contains a significant number of defines, as
DBC macro processing is horrific. Don't know how it compares to
ACE C. Definitely slower than Lightspeed C (from what I can
tell from the ANALOG article).

Some limitations (off the top of my head):

1. Only two pools of identifier names: global and local. The "global"
pool includes anything declared at the outer level, struct/union tags,
and struct/union component names. The "local" pool includes
function arguments, local variables, and labels.

2. No strong type checking (yet, at least).

3. Code produced by new compiler is only slightly more optimal than
that produced by the old DBC compiler. Sigh.

4. Any limitations DBC had that exist.

The object code produced is compatible with the original DBC linker but
not with the original DBC.OBJ. The new version of DBC.OBJ will run anything
produced by the original DBC compiler.

Is anyone interested in this? I'd like to post it, but I'm not sure of
the legalities involved. Any advice?

From: lafitup! <8440827%wwu.edu@RELAY.CS.NET>
To: INFO-ATARI8-REQUEST@SCORE.STANFORD.EDU
Subject: Atari 400 & baud rate / keyboards

I've got two questions:

1) can the Atari 400 handle a 1200 baud modem. I've been told by the
local Atari guy here in Bellingham that the hardware of the old 400
is such that it can't handle a 1200 baud modem. Anybody out there
know for sure if this is true or not?

2) Is there an external keyboard that can be attached to the 400. I had
the membrane board and then upgraded to the b-key keyboard. I see
all the time adverts for replacement keyboards and was wodering if
there was one that would connect or that you could make connect to
the 400.

In response to Dave's note: I have a 400 with 48K memory and a detached keyboard on a ribbon cable. I also have a Ven Tel 1200 bps modem connected through an 850.

I run VT10SQ extensively, and AMODEM when I need file transfer. I would be interested in getting a working Kermit. I tried Chameleon and found that it didn't work perfectly and that I couldn't get used to the horizontal scrolling.

I have wiring diagrams etc somewhere in my files from when I added the keyboard and would be willing to share them with anyone who needs them. Please contact me directly about this.

Concerning VT10SQ: The author retired from MITRE and moved to a trailer park in Florida. I have his address and will write him (USPS) concerning the availability of source code. Will those people who expressed an interest in adding file transfer also please get in touch with me.

Sincerely,

In the May issue of ANALOG there was a little note about the 3.5" disk drive. According to ANALOG ATARI scrapped the 3.5" in favor of a 5 1/4". The drive will be a DS/DD, and compatiable with the Indus, Rana, Trak, etc. Also the ADOS that was being written for the 3.5" in now being rewritten for the 5 1/4" dirve.

Neil, can you confirm or deny this? Please confirm it, as a 5 1/4" DSDD drive would really add more power to my already powerful 1200XL.

Does anyone know if there are any funny interactions between the 4 "voices" on an 800 and it's handling of devices out on the serial bus? I know they're both handled by POKEY, but can't find anything in any of my doc that says they're not independent. Nonetheless, when I've got a serial line open (thru an 850), and try to make noises, the serial line parameters, ie baud rate, and perhaps other things, seem to get completely screwed. Data to/from the port gets garbled, needless to say. Closing and opening the port cleans it up. By picking different voices, I've been able to screw up keyboard reading as well.

Anybody run into anything like this?

If we redesign the disk drive for the 8-bits (possible but not yet definite), it will be done much as described. This makes much more sense than doing a 3.5" drive for the 8-bits -- how would you load existing 8-bit software into a 3.5" drive? By folding the disk in half, perhaps? :-)

439. Re: Is Atari killing the 8 bit?

Newsgroup: comp.sys.atari.8bit
Date: 1987-05-12 17:57:38 UTC
From: neil@atari.UUCP
Message-ID: <730@atari.UUCP>
Source record: 117693

We come again to that perpetual question: is Atari intent on killing the 8-bits?

One way to answer that would be to give you a tour of our warehouse. If you could see the number of 8-bit computers and software in inventory, you'd know we are highly motivated to keep the line going.

Regarding the new XE Game System, which on the first glance is a slap in the face to those who know how powerful the 8-bitters are -- this system is purely a strategic move on our part. In order to keep the 8-bit line going, we must do two things:

1. Get the computers available in more stores, and
2. Get new software developed for them.

Software is not being developed by and large because of problem #1. So which stores do we go to? The mass merchants, who sold the bulk of the hundreds of thousands (not, unfortunately, millions) of Atari 8-bit computers out there, are currently retreating from the computer business. K-Mart carries NO computers. Ditto for Montgomery Wards. And for J.C. Penney's.

On the other hand, these same stores are doing a fabulous business in game systems like Nintendo, Sega, and, of course, Atari.

The solution, from a business point of view, was to develop a product that would be appealing to the mass merchants (and also to the public which buys there), one that also accomplishes the corporate objective of revitalizing the 8-bit line.

So what we have with the XE Game System is essentially a 65XE in disguise. Internally it contains 64K of RAM, the standard OS and BASIC in ROM, two joystick ports, SIO port, etc. It is completely compatible with the current 8-bit line, including software.

Physically it is more appealing to those who don't want a computer but who do want to play games. The main console simply has the 4 console keys from the XE (Start, Select, Option, and Reset), plus the cartridge port and connectors. The keyboard is a separate unit which plugs into the console.

When someone buys the XE Game System, they get the complete package -- console, keyboard, light gun, and 3 programs (including a new version of Sublogic's Flight Simulator including scenery, all on a single cartridge).

We expect stores to do a great business in these. We'll make available the current library of cartridge software, plus we're converting some disk programs into cartridge format for this system. As time goes by, we expect

to see dramatic increases in sales for 8-bit software -- hopefully, this will also include practical applications as well as games. This should in turn encourage developers to create new titles for the 8-bits.

Once things get moving again in the mass merchants, the current supply of 8-bit computers should also get moving through the dealers -- after all, they make a better value than the game systems, and take up less space.

So, those few of you out there who are looking at Atari management as the evil group who are plotting to quash the 8-bit line, you have it all wrong. We're trying hard to keep things moving forward. Without the distribution and the software, no amount of advertising and new hardware development could work. The XE Game System is our best hope to keep things moving.

Source record: 117696

The source of my keyboard is out of business, but I think you can probably use one of those offered by Radio Shack after a little work.

The first requirement is that it must be an unencoded keyboard. That is, pressing a key closes a contact between a pair of wires, as compared to causing a bit stream to be transmitted. If you can't find a keyboard without the keys already wired in the switching matrix, it may be necessary to remove all the wiring from the back of the keys.

Select a keyboard with enough keys. You may find that some of the special function keys, such as TAB, ESC, and CTRL are in a different physical position than on the Atari keyboard. That doesn't bother me. If there aren't enough keys for START, BREAK, etc, these can be implemented off the keyboard with push buttons.

I have the wiring diagrams for the key matrix and will be happy to supply it on request.

How about a little thingie called a TOOL. This TOOL has just one function
in life... to copy files from a disk written under one file format onto
a second disk written using a MUCH improved file format. The Atari 810
file format IS the worst disk format in the industry.

I'm getting married on May 30th, so if it's not ready by then, well...
Right now, I have a working version of the compiler, though it's not
been thoroughly tested yet, I still have two non-trivial things left on my
"goodies" list: constant expressions and decent error handling. I'd
really like to do constant expressions, e.g., "int arry[SIZE+1];" (50/50
at this point). I'm definitely going to punt on the error handling (sorry).

Brad Banko originally volunteered to test a preliminary version of the
compiler, but since he's off the net now, would someone else like to
step in? (First offer goes to Marc Appelbaum unless Brad is out there
somewhere...)

>Will it have
>docs?

Sure, "The C Programming Language" by Kernighan and Ritchie :-). But
seriously, apart from a page or two describing new features and their
limitations, no. That along with the Deep Blue C manual should get you
through.

>Okay......WILL YOU POST IT ON THE NET?

I will, unless someone gives me reason why I shouldn't...

>(By the way, if possible, make it compatible with ACE C's FASTC.COM. This
>program does the P-code optimizing for you.)

This sounds like a great idea. Can anyone tell me if FASTC.COM is compatible
with the P-code described in the documentation that came with Deep Blue
Secrets?

I'm not going to post the sources at first. Maybe later...

By the way, I forgot to mention the compiler does initializers too (static
variables only).

448. kermit and vt10sq

Newsgroup: comp.sys.atari.8bit
Date: 1987-05-15 02:23:29 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8705150223.AA25938@mitre-bedford.ARPA>
Source record: 117702

Marshall:

As you probably know, I run CDY's OMNIVIEW (on an 800XL) here, and use CDY's OmniCom these days, mostly because it includes kermit, xmodem, and most recently, ASCII file capture and built-in Print Screen functions. (And of course you can "capture" to the file named "P:", i.e. the printer, if you wish.) With the current price of OMNIVIEW with 80-column word processor down at $39.95 last I heard, you and others wishing VT100 emulation with kermit ought to consider OMNIVIEW/OmniCom. Incidentally, the graphics emulation is quite a bit more complete, and in my opinion, the character font a little more pleasing, than VT10SQ.

The kermit in OmniCom has worked very well both with VAX kermit and with kermit on a local Zenith-PC based BBS, which are the only two cases I've tried. I've used the xmodem on a couple of other BBSs which don't support kermit, and that has worked very well also.

I believe OMNIVIEW is also available for the 400/800, and of course you could run OmniCom too, since it is disk-based. Should you wish to go this way, you could be "on the air" with kermit almost immediately, as well as having a true 80-column word processor.

Nevertheless, with VT10SQ a Public Domain program I applaud the idea of enhancing it ultimately to have similar features. And by the way, thanks for sending it to me lo those many months ago. I got a lot of use out of it as a vanilla VT100 emulator before I bought OMNIVIEW, but it's a lot more convenient to have everything built into a single program like OmniCom.

449. 1050 disk drive problem

Newsgroup: comp.sys.atari.8bit
Date: 1987-05-15 14:25:01 UTC
From: david1@mhuxu.UUCP
Message-ID: <6492@mhuxu.UUCP>
Source record: 117703

My 3 year old 1050 disk drive died. The on/off led comes on when you turn the switch on, but nothing else happens. Has this happened to anyone else out there? Would something like this be worth getting fixed or are these drives throw away items?

Thanks for any useful info.

Rick Nelson

Source record: 117704

In response to: John R. Dunning <jrd@STONY-BROOK.SCRC.Symbolics.COM>
The 'voices' on the 800 and the serial bus ARE controlled by the same chip.
If I remember correctly, one voice channel is used in sending serial data out to the serial output pin, and another is used in receiving data from the serial input pin. I was going to say that this still leaves two voices left for making noises, but I think the voices are linked together two at a time in order to get better frequency resolution for the serial bus frequencies.
So you can't use the voices for making sounds without screwing up the serial bus setup, i.e., they're not independent. Details are given in the hardware (or operating system manual) if you can locate a copy of that.

451. driver loader for atari 835 modem OR cheaper 850 replacement

Newsgroup: comp.sys.atari.8bit
Date: 1987-08-07 13:00:05 UTC
From: feb@cblpe.ATT.COM
Message-ID: <596@cblpe.ATT.COM>
Source record: 117505

I've been using Chameleon with my 800 and an atari 835 modem, but now I'd like to switch to the new Kermit-65 that was just posted. I don't think this will work because the driver for the 835 doesn't get loaded when the system boots, a program has to cause it to be loaded (ie, it does NOT behave like an 850.)

So, what I'd like to know is, does anyone have a driver loader for the 835 that I can 'prepend' to Kermit-65 to use it with the 835 modem?

An even better question is: what the best alternative to getting a real 850 (they're what, $130 now? way too much) ?

I'm not in love with the 835 and I'll switch at the first hint of a cheaper serial interface (no printer interface required, there's one in my disk drive ; anyone remember Trak drives?)

Anyone want to buy a lightly used, slightly useless (I mean we're talking 300 baud!) 835 modem. Comes complete with Telelink II cartridge. Works with version ?? (I forgot) of chameleon.

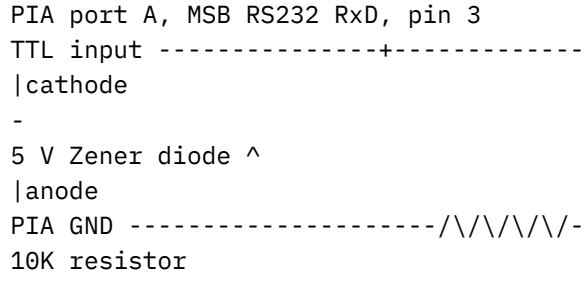
Subject: Re: Impending release of Kermit-65
To: info-atari8@score.stanford.edu
```

In private correspondence with John Dunning the chicken-and-egg problem
came up of getting _a_ Kermit, any Kermit, onto a micro that doesn't have
one. Once you have even the most kludgeful ancient copy you can always
use it to snag a different version. Experienced modem users will have
at least one program that can capture stuff coming off the modem and dump
it to disk files; these people will have no problem reading UUDECODE.BAS
and the encoded KERMIT.UUE, and running uudecode to create KERMIT.COM (or
whatever the filenames are). These people are not who I'm concerned about.
A fair number of people will be relatively new to modeming and will have
only dumb-terminal software, either booted off the modem or from a disk
that came with the modem. What they need is something that will vacuum
characters off the modem port and tuck them away in memory, and then
write that large buffer out to disk at the end. The right way to do this,
of course, is to figure out how to get characters back from the modem and
embed that in the main program's loop, but the variety of modems and
interfaces means that you will have to deal variously with packetized/
serialized/parallelized/nybblized data and be able to provide simple
instructions (remember, this is supposed to be a novice user) that say,
here, type in this one-screen BASIC program and do thus-and-so to get
KERMIT.UUE and UUDECODE.BAS onto disk. Then you're home free. But
the instructions are bound to miss somebody's modem or interface or be
not quite debugged so that Joe_luser is guaranteed to understand them
and do the right thing, or some exception will pop up, or whatever.
Basically, this would be easier if we had a standard environment. Hmmmm.

Everyone has a PIA. And just about everyone reading this newsgroup is
reading it using an account on either a university or company computer.
This computer almost certainly has at least _one_ RS232 port that could
be borrowed at least _once_ for a special occasion when you bring in
your Atari to download Kermit to it. ('Course, you probably have a
perfectly good 232 snaking up to your desk even as you read this and
using it for other purposes it would be _no_ _big_ _deal_.)
SOOooo, having justified my reasoning in the hope of warding off
massive flames about all the rules I'm about to break below, on to
the meat of the article. This is my proposal: Have someone write
a short 6502 routine that shifts bits in from port A of the PIA and
on cue calls CIO to write the whole mess out to disk. Or let BASIC
do the disk I/O, I really don't care. Following is the level-shifter
that prompted all these musings:



1E3 apologies for not posting the joyport pinouts! John Dunning said he'd
look them up tonight; I just don't have that info, here.

I messed around with this circuit a fair amount before posting it and am
pretty confident that it shouldn't damage any equipment, but don't blame me
when you kill your Atari or your host's terminal driver. Be particularly
careful that you don't short out the 10K or insert the Zener backwards.
The band on the +----++ |\-+
diode marks the -----| ||------- -----| >|-------
cathode end: anode +----++ cathode anode |/ +- cathode
I don't see how I could make it much clearer than that. You've been warned.

The 10K simply protects the RS232 driver from having to drive too much
current. I initially tried it between RxD and the diode but found that
I couldn't drive the TTL input to ground: the diode would open up and the
input would just float high. It currently limits current to a little over
a mA. Feel free to use larger values.

The Zener protects the TTL input from ever seeing any voltage outside the
range (5V, -0.7V). I used Radio Shack Cat. No. 276-565, a 5.1V Zener, and
had no problems. Presenting a -0.7V input isn't actually quite Kosher
(you're theoretically never supposed to go below either 0 or -0.3V), but it's
no great stress either. Ideally you should pick about a 4.2V Zener that
turns on at 0.3V instead of 0.7V. Don't go above 5.1.

Theory of operation: When pin 3 is between -12V and -0.7V, the diode
conducts and the TTL input is connected to ground (actually it sees -0.7,
not 0 -- I measured -0.5 for my Zener). The -12V or whatever is across a
10K, so ~1mA flows. This is the normal (no data) case. When pin 3 is
between -0.7V and 5V, the Zener is an open circuit and the TTL input is
connected to pin 3. Somewhere in this region the TTL will discriminate
between logic low and logic high (my 7400 turned on at pin 3= 0.7V; it also
exhibited a little hysteresis: it didn't turn off until pin 3 dropped to
about 0.2V). When pin 3 is between 5V and 12V, the diode zeners, preventing
the voltage across it from _ever_ going above 5V. Excess voltage goes
across the 10K, letting as much as 0.6mA of current flow. This is the
case for data bits being sent or break being held.

I should mention that I haven't actually hooked this up to a PIA (because
I'm living about 60 miles away from my Atari and we don't have any PIA's
around here), but I _have_ tested this with real 12V RS232's and real low
power Schottkey TTL circuits: a 7400, with input going to a NAND gate and
another one used to double-invert to drive a LED. Never fried the '00,
and it seemed to work fine from 110 to 9600 baud (use a small (~40 ohm)
resistor on the LED to catch those 9600 flashes).

So, there's the hardware part: 2 whole parts and probably way more explanation
than was necessary. Now will someone out there with better access to an Atari
than me hack out the timing needed to shift bits in from the PIA and buffer
them up? No need to do spiffy autobauding or anything. To get the inital
timing down, I suggest you run a tight loop of fetch data-bit from PIA,
store, increment address to store to, loop. Looking at how long values
repeat for will give you an idea of how many instructions you can execute
before the bit changes, and how stable that number is.

Good luck!

Subject: New Atari Products
To: info-atari8@score.stanford.edu

Hi. I'm interested in keeping my Atari 8bits useful in my home with it's
new Unix machine. I have been putting up with VT10-squared and that's
simply not acceptable. I would like to get an 80-column box as soon as
possible, assuming it has about the quality of an IBM mono display.

(PS. For the record, I checked, character by character, bit by bit, the char]
sets of Omnicom and VT10sq and they are virtually identical, at least what we
have, so any comments to "easier readability" of one or the other are
completely in the minds of the viewer. Then again, how many ways can you
MAKE a 3 bit wide character set!)

Also, the 1200-baud modem was announced some time ago and we haven't
heard much since, so can we safely assume this is not coming out?

Meanwhile, I kinda expected to see the new 8bit drive a lot sooner than
this, since Atari has been selling an "XL look" drive to go with it's
XEs and they _can't_ like that. Does anyone know where I can pick this
up as well? I'd like to retire my 810 to the kitchen with the 400 as a
local drive.

Please filter out any vaporware places. We've already discovered a few
advertising vapor-software and hardware who will take your money but
have nothing to ship. Any field comments on the quality of the 80-col
output versus "industry standard" 640 X 400 output on other mono-text
systems (IBM, ST) would be appreciated.

Subject: More Info on CC8
To: info-atari8@score.stanford.edu

A few more things about this version of the compiler:

I've noticed a couple of "features" CC8 has inherited from Deep Blue
C. One is that the "for" statement will not accept null expressions.
Thus,

for (; ;)

needs to be written

for (0; 1; 0)

Ugh! Will be fixed next version...

The other is that the compiler also insists that the expression to the
left of a [be of type pointer or array. However, the definition of C
states that the expression "a[23]" is the same as "23[a]" (since it is
also equivalent to "*(a + 23)"). This may not get fixed.

A couple of other tidbits:

o the maximum number of array bound that can be declared is 6 (7
if "array of ... array of int|char"). More and the compiler
runs out of space for type descriptors. Don't tell me 6 isn't
enough! :-)

o The compiler understands "left curly", "right curly", and
"tilde" (meaning whatever graphic or control character they
happen to map to in ATASCII).

o add "Constant expression may be used as case label" to the
future features list.

Subject: SHRINK, the one that works!
To: info-atari8@score.stanford.edu

Just great. The uuencoded "shrink" program I posted doesn't work! I'm
destined to make it up to everyone. (I hate uuencode anyway.) What
I've done here is written a "C" program that encodes/decodes binary
files (the program's mine but I got the algorithm from _Unix_World_).
Just split this posting up into seperate files, compile the encode/decode
program, and run it on the coded "shrink" file below. I made sure it
works this time, it does! Have Fun!
BTW...I put a ----CUT HERE--- at the end of this posting so you'll know
that you got the complete file.

Gould Inc., Computer Systems Division, in Sunny South Florida
** The opinions (if any) expressed are my own. **
...seismo!gould!pkopp OR ...akgua!ucf-cs!novavax!gould!pkopp

And remember: A path is a thing that you have running
between two shrubberies of slightly different heights.

The encode/decode program:

```
#include<stdio.h>

main(argc,argv)

int argc;
char *argv[];

{
FILE *fopen(),*in,*out;
int c;
int i=0;
int choice;

if(argc < 4)
{
printf("\nusage: %s [-e -d] in_file out_file\n",argv[0]);
printf("where: -e = encode file\n");
printf(" -d = decode file\n");
exit();
}

if((in=fopen(argv[2],"r")) == NULL)
{
printf("Error opening input file\n");
exit();
}
if((out=fopen(argv[3],"w")) == NULL)
{
printf("Error opening output file\n");
exit();
}

if(!strcmp(argv[1],"-e")) /* Encode File */
{
while ((c = fgetc(in)) != EOF)
{
fprintf(out,"%02x", c);
if (++i == 30)
{
fprintf(out," \n");
i = 0;
}
}
fprintf(out," \n");
exit();
```

```
}

else if(!strcmp(argv[1],"-d")) /* Decode File */
{
while(fscanf(in,"%2x", &c) != EOF)
fputc(c,out);
exit();
}
fclose(in);
fclose(out);
}
```

And now, the coded version of "shrink":

in article <596@cblpe.ATT.COM>, feb@cblpe.ATT.COM (Franco Barber) says:
->
-> I've been using Chameleon with my 800 and an atari 835 modem.

Same here! Version 4.03 to be exact.

-> I'd like to switch to the new Kermit-65 that was just posted. I don't
-> think this will work because the driver for the 835 doesn't get loaded
-> when the system boots, a program has to cause it to be loaded (ie, it
-> does NOT behave like an 850.)
->
-> So, what I'd like to know is, does anyone have a driver loader for the
-> 835 that I can 'prepend' to Kermit-65 to use it with the 835 modem?
->

I've tried. Kermit-65 won't work with the 835 modem. I downloaded the
'bare' version of Kermit-65 and prepended the 835's "T" handler onto it
with DOS (copy using the /a option). NO GO! It's too bad...it looks
like a well written program. It loaded ok; I even managed to browse
around and play with some of the functions (80 column screen, status,
set, etc.). It didn't like it too much when I tried "connect."

Oh well, someday I'll break down and invest in some kind of RS232 hardware
and a REAL (I can't even set word size or parity) modem.

457. Good news and bad news

Newsgroup: comp.sys.atari.8bit
Date: 1987-08-10 15:07:00 UTC
From: jrd@STONY-BROOK.SCRC.SYMBOLICS.COM
Message-ID: <870810110707.0.JRD@GRACKLE.SCRC.Symbolics.COM>
Source record: 117511

The good news is that my post of Kermit-65 got out to the world intact, and seems to be going over pretty well. The bad news is that a couple of bugs (one quite serious; binary mode transfers are busted) have already surfaced.

The question of the day: What's a happy medium between getting these bugs fixed in a timely fashion (desirable) and bombarding the net with 100K postings (not desirable)? I think my preference would be to wait a while before posting a revised version, in order to really get some things fixed. Assuming the concensus agrees, but some of you out there really need to get that binary bug fixed for the thing to be usable, I'd be willing to ship individual copies to people on request.

As usual, any feedback is welcome.

I have a XEP80 here (got because of my developer status) and can say it is
as good as any true 80 column display can get. One comment though...
the XEP will support underline, inverse video, flashing, and graphics, but
will not support any combination of the above. In other words you can't
have flashing text and underlined text on the same screen. One character
in missing in the XEP...the tilde! oops.

Subject: driver loader for atari 835 modem OR cheaper 850 replacement
To: info-atari8@score.stanford.edu

I've been using Chameleon with my 800 and an atari 835 modem, but now
I'd like to switch to the new Kermit-65 that was just posted. I don't
think this will work because the driver for the 835 doesn't get loaded
when the system boots, a program has to cause it to be loaded (ie, it
does NOT behave like an 850.)

So, what I'd like to know is, does anyone have a driver loader for the
835 that I can 'prepend' to Kermit-65 to use it with the 835 modem?

An even better question is: what the best alternative to getting a real
850 (they're what, $130 now? way too much) ?

I'm not in love with the 835 and I'll switch at the first hint of a
cheaper serial interface (no printer interface required, there's one in
my disk drive ; anyone remember Trak drives?)

Anyone want to buy a lightly used, slightly useless (I mean we're talking
300 baud!) 835 modem. Comes complete with Telelink II cartridge. Works
with version ?? (I forgot) of chameleon.

Does anyone happen to know what these characters would be on the Atari?
I would like to know so that I can redefine them on my text editor.
Post any reply to the net or send directly to me.

Mail-From: G.ABRAMS created at 9-Aug-87 14:19:15
Date: Sun 9 Aug 87 14:19:15-PDT
From: Info-Atari Moderator <G.ABRAMS@SCORE.STANFORD.EDU>
Subject: Revised information about info-atari
To: info-atari8@SCORE.STANFORD.EDU, info-atari16@SCORE.STANFORD.EDU

The WELCOME message for info-atari has been revised to reflect new
status (or aspirations). Please retain this message in your files for
future reference.

The archives in directory info-atari on score.stanford.edu still exist;
but I can't guarantee for how long. Older archives are in directory
score/info-atari on labrea.stanford.edu . Note that Score runs under
TOPS-20 and Labrea is a UNIX system.

1. Welcome

- -------

Welcome to info-atari.

2. Sending Messages

- ------- --------

You may send messages to all "subscribers" by address-
ing it to
info-atari8@score.stanford.edu
and/or
info-atari16@score.stanford.edu

Administrative messages should be sent to
info-atari{8,16}-request.

Please do NOT send general messages to this address. Your
moderators get enough mail as it is!

3. Ground Rules

All messages should be in good taste. Commercial messages and advertisements are not permitted. When answering a question, please consider carefully whether the answer should go to the whole list, or just to the person who asked the question.

The following ground rules should make the use of this (or of any other) mailing list much easier:

* never send a message that a totally irrelevant to the mailing list's purpose to a mailing list. This especially includes any expressions of irritation at another list member.

* never forward a message that is totally irrelevant to the mailing list's purpose to a mailing list.

* when replying to a message on a mailing list, reply only to the sender of the message unless the reply is of interest to the entire mailing list.

* avoid inserting the message being replied to in a reply, especially in a message going to a mailing list. The context of the reply should be clear from *your* reply and from various mailer functionalities such as Message-ID.

* when replying to an earlier reply that violates the previous rule, ABSOLUTELY DO NOT make matters worse by adding your own violation.

4. LISTSERV

LISTSERV provides a number of features which you can access by sending mail (note) to LISTSERV. Only the barest minimum are described herein. On Bitnet messages should be sent to your nearest LISTSERV (the one from which you receive the info-atari digests). (If your address is not on Bitnet, an address for file servers is given below.) All mail sent to LISTSERV contains command lines. LISTSERV will respond by return mail. No subject is necessary in such mail. For more information send the command
INFO

4.1. List Names

The list_name for 16-bit Ataris is INFO-A16. The list_name for 8-bit Ataris is INFO-A8. These list names are used by Bitnet addressees for subscribing and unsubscribing and by everyone for obtaining back copies of news digests.

The list_names for programs stored in the archives are
PROG-A16 and PROG-A8.

4.2. (Un)Subscribing

If you are on Bitnet you may add or remove yourself
from the distribution list. It would greatly convenience
the moderators if you would do so when you no longer wish to
receive digests.

The command to join the list is
SUBSCRIBE list_name User_name

The command to remove yourself from the list is
UNSUBSCRIBE list_name

Note that the list was established with all user_names
unknown. To enter your name, send a SUBSCRIBE command.

It would be most convenient if users took care of their
own subscribing and unsubscribing, but messages to INFO-
ATARI-REQUEST{8,16}@SCORE.STANFORD.EDU will still be
accepted.

4.3. File Server (Archives)

The following service is being installed beginning
February 1987; we will announce when everything is in place
and "known" to be working.

All messages are in the archives. In addition, some
contributed programs are also there. You can obtain copies
of files from LISTSERV by sending a message in the specified
format.

If you are on ARPAnet (or gatewayed to it), your mail
should be addressed to
LISTSERV%CANADA01.BITNET@WISCVM.WISC.EDU

To obtain a list of files in the file server, the com-
mand is
INDEX list_name

The command to obtain a specific file is
GET list_name file_name

for example,
GET INFO-A16 87-00076

If you want to learn more, send the message
HELP

Date: Sun, 9 Aug 87 17:00:37 EDT
From: abrams%community-chest.mitre.org@gateway.mitre.org
To: g.abrams@score.stanford.edu
Subject: new welcome message

1. Welcome

– -------

Welcome to info-atari.

2. Sending Messages

– ------- --------

You may send messages to all "subscribers" by address-
ing it to
info-atari8@score.stanford.edu
and/or
info-atari16@score.stanford.edu

Administrative messages should be sent to
info-atari{8,16}-request.

Please do NOT send general messages to this address. Your
moderators get enough mail as it is!

3. Ground Rules

– ------ -----

All messages should be in good taste. Commercial mes-
sages and advertisements are not permitted. When answering a
question, please consider carefully whether the answer
should go to the whole list, or just to the person who asked
the question.

The following ground rules should make the use of this
(or of any other) mailing list much easier:

* never send a message that a totally irrelevant to
the mailing list's purpose to a mailing list. This
especially includes any expressions of irritation at
another list member.

* never forward a message that is totally irrelevant
to the mailing list's purpose to a mailing list.

* when replying to a message on a mailing list, reply
only to the sender of the message unless the reply
is of interest to the entire mailing list.

* avoid inserting the message being replied to in a
reply, especially in a message going to a mailing
list. The context of the reply should be clear from
your reply and from various mailer functionalities
such as Message-ID.

* when replying to an earlier reply that violates the
previous rule, ABSOLUTELY DO NOT make matters worse
by adding your own violation.

4. Archives

Archives are kept in several places in formats avail-
able to everyone. As described below, if you are on
ARPANET/DDN you will probably find it more convenient to
retrieve files from the archive on radc-softvax.arpa using
FTP. If you are not on ARPANET/DDN, or are unable to use
FTP, you will be able to retrieve files from archives dis-
tributed over several Bitnet hosts by sending mail (notes)
to a program called LISTSERV.

4.1. Archives on radc-softvax.arpa

Files from radc-softvax.arpa are available by FTP. FTP
will work only for hosts directly connected to ARPANET/DDN.
Please obtain local documentation and advice for the FTP
user programming running on your host. There are two direc-
tories under the anonymous account. One for atari8 and one
for atari16.

FTP to radc-softvax using login:guest and
password:guest. To get the current list of available atari16
files do a 'get atari16/files.doc'. All of the atari16 files
are stored in the atari16 subdirectory. If you need any
other information, contact Marc Poulin.

The archive is maintained by Rodney Peck (Peck@radc-
multics.arpa) and Marc Poulin (Poulin@radc-multics.arpa or
Archives@radc-softvax.arpa).

4.2. LISTSERV

LISTSERV provides access to files for everyone who can
send mail, independent of their location. Note, however,
that intermediate notes have been known to refuse to handle
long messages or have damaged them in transit. LISTSERV
provides a number of features which you can access by send-
ing mail (note) to LISTSERV. Only the barest minimum are
described herein. On Bitnet messages should be sent to your
nearest LISTSERV (the one from which you receive the info-
atari digests). (If your address is not on Bitnet, an
address for file servers is given below.) All mail sent to
LISTSERV contains command lines. LISTSERV will respond by
return mail. No subject is necessary in such mail. For
more information send the command
INFO

4.2.1. List Names

The list_name for 16-bit Ataris is INFO-A16. The list_name for 8-bit Ataris is INFO-A8. These list names are used by Bitnet addressees for subscribing and unsubscribing and by everyone for obtaining back copies of news digests. The list_names for programs stored in the archives are PROG-A16 and PROG-A8.

4.2.2. (Un)Subscribing

If you are on Bitnet you may add or remove yourself from the distribution list. It would greatly convenience the moderators if you would do so when you no longer wish to receive digests.

The command to join the list is
SUBSCRIBE list_name User_name

The command to remove yourself from the list is
UNSUBSCRIBE list_name

It would be most convenient if users took care of their own subscribing and unsubscribing, but messages to INFO-ATARI-REQUEST{8,16}@SCORE.STANFORD.EDU will still be accepted.

4.2.3. Accessing Program & Digest Archives

All digests are in the archives. There is a separate program library. You can obtain copies of files from LIST-SERV by sending a message in the specified format.

If you are on ARPAnet (or gatewayed to it), your mail concernin 16-bit Atari information should be addressed to
LISTSERV%CANADA01.BITNET@WISCVM.WISC.EDU

Mail concernin 8-bit Atari information should be addressed to
LISTSERV%TCSVM.BITNET@WISCVM.WISC.EDU

To obtain a list of files in the file server, the com-mand is
INDEX list_name

The command to obtain a specific file is
GET list_name file_name

for example,
GET INFO-A16 87-00076

If you want to learn more, send the message
HELP

4.2.4. LISTSERV Moderators

The person to contact if you are having problems (un)subscribing is Harry Williams (harry@marist.bitnet). The moderator of the 16-bit digest archives is Peter Jasper-Fayer (sofpjf@uoguelph.bitnet). The moderator of the 16-bit program archives is Richard Werezak (carson@mcmaster.bitnet). The moderator of the 8-bit archives is John Voigt (sysbjav@tcsvm.bitnet). The moderator of the 8-bit program archives is Arnold de Leon (adeleon@hmcvax.bitnet).

4.2.5. Information Concerning 16-bit Archive Organization

The digests are numbered sequentially as they come in. Sometimes the files arrive here out of order, or with missing ones, or with extra ones or with mail from BITNET users requesting information. Often the moderator has to logon to LISTSERV and re-name the files according to the "Subject:" line within it. Those "Subject:" lines are what end up in the indexes (in both "-A16" lists)

The program files are largely extracts from the digests (INFO-A16). As far as possible, they are numbered the same as the digests they came from. Other programs were inserted somewhere in the list. The numbers of these "inserted" files were selected so that they would appear in the index at about the correct CHRONOLOGICAL sequence. If no programs were included in the digests, and nocontributions were received, then those spaces in the index numbers were left blank.

Please post to net if you know. I also
need to generate tildes and the 800XL
is missing them.

Subject: Re: driver loader for atari 835 modem OR cheaper 850 replacement
To: info-atari8@score.stanford.edu

in article <596@cblpe.ATT.COM>, feb@cblpe.ATT.COM (Franco Barber) says:
->
-> I've been using Chameleon with my 800 and an atari 835 modem.

Same here! Version 4.03 to be exact.

-> I'd like to switch to the new Kermit-65 that was just posted. I don't
-> think this will work because the driver for the 835 doesn't get loaded
-> when the system boots, a program has to cause it to be loaded (ie, it
-> does NOT behave like an 850.)
->
-> So, what I'd like to know is, does anyone have a driver loader for the
-> 835 that I can 'prepend' to Kermit-65 to use it with the 835 modem?
->

I've tried. Kermit-65 won't work with the 835 modem. I downloaded the
'bare' version of Kermit-65 and prepended the 835's "T" handler onto it
with DOS (copy using the /a option). NO GO! It's too bad...it looks
like a well written program. It loaded ok; I even managed to browse
around and play with some of the functions (80 column screen, status,
set, etc.). It didn't like it too much when I tried "connect."

Oh well, someday I'll break down and invest in some kind of RS232 hardware
and a REAL (I can't even set word size or parity) modem.

From: John R. Dunning <jrd@STONY-BROOK.SCRC.Symbolics.COM>
Subject: Good news and bad news
To: Info-Atari8@SCORE.STANFORD.EDU

The good news is that my post of Kermit-65 got out to the world intact,
and seems to be going over pretty well. The bad news is that a couple
of bugs (one quite serious; binary mode transfers are busted) have
already surfaced.

The question of the day: What's a happy medium between getting these
bugs fixed in a timely fashion (desirable) and bombarding the net with

100K postings (not desirable)? I think my preference would be to wait a while before posting a revised version, in order to really get some things fixed. Assuming the concensus agrees, but some of you out there really need to get that binary bug fixed for the thing to be usable, I'd be willing to ship individual copies to people on request.

As usual, any feedback is welcome.

The only help I can add here is that the right bracket is the clear screen
character (esc-clear), and the left curly is the spade symbol
(CTRL- [colon]). I don't know what the tildes are.

To: info-atari8@score.stanford.edu
```

Please excuse my ignorance (and all that). A friend of mine recently
purchased an Atari-6000-X-something-or-other. He's trying to get it to
do stuff in Basic (of course).

Now, he can get it to read integers from the keyboard ("input i"), but
he says he can't get it to read strings at all ("input a$" does NOT work).

I personally haven't touched a line of basic in about 3 years or so (and
that was under extreme protest) and I don't think I've even SEEN an
Atari (well, I probably have, but....), so I don't know the idiosyncracies
of his machine.

So -- who out there can send me mail with an example of how to read a
string on this machine? Please -- if you program on this machine and
know how to read a string, email me an example and I'll send it down
to him.

Don't bother to followup here -- I don't subscribe to this newsgroup.

You can buy an expansion board that plugs into the Parallel Bus on
the back of the 600XL, this would bring the 600XL to 64K. I believe
Atari still sells them. Your best bet would be to write to Atari
Customer Service.

To: info-atari8@score.stanford.edu
```

Please excuse my ignorance (and all that). A friend of mine recently
purchased an Atari-6000-X-something-or-other. He's trying to get it to
do stuff in Basic (of course).

Now, he can get it to read integers from the keyboard ("input i"), but
he says he can't get it to read strings at all ("input a$" does NOT work).

I personally haven't touched a line of basic in about 3 years or so (and
that was under extreme protest) and I don't think I've even SEEN an
Atari (well, I probably have, but....), so I don't know the idiosyncracies
of his machine.

So -- who out there can send me mail with an example of how to read a
string on this machine? Please -- if you program on this machine and
know how to read a string, email me an example and I'll send it down
to him.

Don't bother to followup here -- I don't subscribe to this newsgroup.

The only help I can add here is that the right bracket is the clear screen
character (esc-clear), and the left curly is the spade symbol
(CTRL- [colon]). I don't know what the tildes are.

I don't /know/ of any public documentation on 2600 internals, but that
doesn't mean there isn't any. But most of the documentation was
'stolen' from Atari, or reverse-engineered, and was kept secret. You
still need to sign a non-disclosure to get the official docs from Atari.

The machine is INCREDIBLY difficult to program. It's a 6507 with 128
bytes of RAMa PIA, abaroque video chip, and next to nothing else.
The keyword here is PAIN. But there are a lot of base units out there....

re: PD wordprocessors for Atari:

Textpro is another PD wordprocessor based on the Speedscript program someone already mentionned. Textpro has some features that no other Atari text processor has. I am not intimately familiar with it yet, but it has a keyboard macro feature, so that strings of keystrokes INCLUDING EDITOR COMMANDS can be assigned to single keys. That can be a very powerful feature. There is a version that allows room for modem handlers so it can be run while a modem is active. And it features an exit to DOS for users of command line DOS's.

Speedscript itself has a good point that should be mentionned: it has a uniquely legible text, using the special Antic mode 6 (I think), with an exceptionally clear character set. It is the easiest on the eyes of all Atari 8bit word processors in my opinion -- not bad at all, for limited word processor use.

472. FROST BASIC (Turbo BASIC for the 800).

Newsgroup: comp.sys.atari.8bit
Date: 1987-08-13 02:51:03 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8708130251.AA05589@mitre-bedford.ARPA>
Source record: 117526

At last, I have FROST BASIC online, in uuencoded, SHRUNK form.
Because of the large number of requests, I will post it. The file is
about 100K bytes long, so I have broken it into four parts. They will
appear, hopefully, as the next four messages from me to the net.

Part 1 includes instructions for assembling the four parts. Basically
(so to speak) you have put the parts back together, uudecode, and unSHRINK.
However, the full uuencoded file is over 100K bytes, which WILL NOT FIT on
a Single Density disk. So you will have to use enhanced density or double
density, or else you will have to uudecode the four parts separately and
only then reassemble them. That can be done with DOS using the /A "Append"
switch as you copy Parts 2, 3, and 4 in succession onto the tail end of the
file you are assembling. Part 1 contains slightly more explicit instructions.
By the way, if you use the second method, it might be a good idea to
copy the assembled file to another file to get the "bubbles" out. I.e.
when you copy with append, there typically are less than full sectors at
the junctions (except with the smarter DOSes), and when you copy the file
this gets corrected.

Owners of the XL or XE machines may want to capture this program (a) for
friends with an 800, or (b) in case YOU later get an 800, or (c) in case you
want to run Turbo BASIC with a DOS like SpartaDOS or DOS-XL or OS/A+, which
need space under the ROM and so are incompatible with Turbo BASIC XL.

Enjoy! And thanks again to Ulrich Lang of West Germany, who very kindly
mailed the disk version of FROST BASIC across the Atlantic for our benefit.

Anybody who absolutely has to have a disk version mailed to them, please
notify me again and I will try to get it mailed in a few days. I'll check my
files to see if anybody already told me they had to have a disk. Please
try to manage to get the program via the net, perhaps with the help of a
local friend, but if you MUST have it mailed, I'll be glad to help you out.

The way to develop for the system is to use a 1200XL and a few odds and
ends that you make yourself. (a static ram chip on a cart board that the
2600 would see as a ROM is a good place to start.) Use MAC-65.
That is the only assembler that will cut it.

>

I have successfully obtained a set of documents from Atari on programming the
2600 game system. It mostly covers programming the TIA but gives a general
overview of the system. Also you will find my notes on the 2600 helpful.
I will post these to the net. The person that you want to talk to
at Atari is Tom Sloper. Hope this helps.

Rich A.

P.S. If you do write a game for it, Tom Sloper would be very interested in it.

To: info-atari8@score.stanford.edu
Subject: FROST BASIC (Turbo BASIC for the 800).
Date: Wed, 12 Aug 87 22:51:03 EDT
From: jhs@mitre-bedford.ARPA

At last, I have FROST BASIC online, in uuencoded, SHRUNK form.
Because of the large number of requests, I will post it. The file is
about 100K bytes long, so I have broken it into four parts. They will
appear, hopefully, as the next four messages from me to the net.

Part 1 includes instructions for assembling the four parts. Basically
(so to speak) you have put the parts back together, uudecode, and unSHRINK.
However, the full uuencoded file is over 100K bytes, which WILL NOT FIT on
a Single Density disk. So you will have to use enhanced density or double
density, or else you will have to uudecode the four parts separately and
only then reassemble them. That can be done with DOS using the /A "Append"
switch as you copy Parts 2, 3, and 4 in succession onto the tail end of the
file you are assembling. Part 1 contains slightly more explicit instructions.
By the way, if you use the second method, it might be a good idea to
copy the assembled file to another file to get the "bubbles" out. I.e.
when you copy with append, there typically are less than full sectors at
the junctions (except with the smarter DOSes), and when you copy the file
this gets corrected.

Owners of the XL or XE machines may want to capture this program (a) for
friends with an 800, or (b) in case YOU later get an 800, or (c) in case you
want to run Turbo BASIC with a DOS like SpartaDOS or DOS-XL or OS/A+, which
need space under the ROM and so are incompatible with Turbo BASIC XL.

Enjoy! And thanks again to Ulrich Lang of West Germany, who very kindly
mailed the disk version of FROST BASIC across the Atlantic for our benefit.

Anybody who absolutely has to have a disk version mailed to them, please
notify me again and I will try to get it mailed in a few days. I'll check my
files to see if anybody already told me they had to have a disk. Please
try to manage to get the program via the net, perhaps with the help of a
local friend, but if you MUST have it mailed, I'll be glad to help you out.

> I am basically interested in finding out how the whole thing works, with an
> eye to maybe writing a game for it.

I don't /know/ of any public documentation on 2600 internals, but that
doesn't mean there isn't any. But most of the documentation was
'stolen' from Atari, or reverse-engineered, and was kept secret. You
still need to sign a non-disclosure to get the official docs from Atari.

The machine is INCREDIBLY difficult to program. It's a 6507 with 128
bytes of RAMa PIA, abaroque video chip, and next to nothing else.
The keyword here is PAIN. But there are a lot of base units out there....

476. WISCVM going away?

Newsgroup: comp.sys.atari.8bit
Date: 1987-08-13 13:43:00 UTC
From: jrd@STONY-BROOK.SCRC.SYMBOLICS.COM
Message-ID: <870813094353.1.JRD@GRACKLE.SCRC.Symbolics.COM>
Source record: 117530

What effect will the threatened disappearance of WISCVM have on the distribution of mail, and, more important to me, the program archives? Is the implication that there really will be a *complete* separately maintained archive on RADC-SOFTVAX or Score or something, as opposed to relying on LISTSERVs?

477. Monitor question

Newsgroup: comp.sys.atari.8bit
Date: 1987-08-13 13:46:00 UTC
From: jrd@STONY-BROOK.SCRC.SYMBOLICS.COM
Message-ID: <870813094639.2.JRD@GRACKLE.SCRC.Symbolics.COM>
Source record: 117531

What, if any, recommendations can anyone give me about decent monitors for 8-bitters? I'd much prefer color, though I'd like to hear what's good in mono, too. Thanks.

478. Is there a vi editor for the 8-bits?

Newsgroup: comp.sys.atari.8bit
Date: 1987-08-13 16:03:51 UTC
From: pkopp@potpourri.UUCP
Message-ID: <558@potpourri.UUCP>
Source record: 117532

I just saw a posting in comp.sys.atari.st. The poster asked if there was a "vi" style/type editor for the st. I've had the same question in mind for quite awhile but I would like to know if one exists for the 8 bits. I know there's one for the IBM PCs but that's the *only* one I've ever seen on micros. I don't expect a full featured vi editor...even someones hack in assy. language (or even better, in ACTION!) would be nice.

82 TECH TIPS
This section is a collection of tips and short programs from readers or collected from various Users Groups newsletters.

Coming next month: Football Predictor, Antic TelePrompter, Checkbook Balancer & Educational Bonus Games.

Comments: Regarding my comments last month, I'm happy to report that Analog Computing did ship a combined July/August issue about the end of July. They still deny that they have any financial difficulty and claim that this will help bring the release date ahead of the cover date. I don't see how it changes anything since they were a month late in getting it out. Maybe going back to a bi-monthly publication schedule would help both ANTIC and Analog Computing, but I know they wouldn't want to do it.

480. Requesting information about the 800 compatible computers

Newsgroup: comp.sys.atari.8bit
Date: 1987-08-13 19:57:34 UTC
From: daves@brspyr1.BRS.Com
Message-ID: <1597@brspyr1.BRS.Com>
Source record: 117534

I own a 48K Atari 800 system with an 850 interface, 810 single density disk drive, and about 50 disks worth of programs. (Also a Gemini printer and modem, but they're attached to my Zenith Z-150 right now...)

The 800 was damaged when I was travelling. It exhibits the following symptoms; the bottom row of keys on the left-hand side of the keyboard (Z,X,C,V) give no response when pressed, and pressing either shift key causes the cursor to do a "carriage return -- linefeed" sequence.

I have taken the machine apart, reseated everything I could, and cleaned the contacts on the keyboard's pc board, but to no avail. As it is now, the 800 is useless for anything except bootable games that use the joystick.

As I see it, I have several options;

1) Try to get it repaired. I've seen ads in Antic for a company that will repair (or replace) an Atari 800 for 39.95 inclusive. Has anyone dealt with this company? (They also sell replacement chips boards, and repair manuals.)

2) Scrap the current 800 and buy a used 800. Around here (Albany, New York area), complete systems are going for $200-500 depending on what's included. I don't really need a complete system (even though another disk drive or two would be nice...), and $200 is stretching my intended budget for this.

3) Scrap the current 800 and buy a compatible machine such as an 800XL, 65XE, or 130XE. Are all of these compatible with the 800? Will they work with my existing hardware peripherals? Will my software work on these machines? What are the advantages and disadvantages of each machine? I understand that the extra memory in the 130XE can be used as a ram disk. Is this true? I've seen prices in Antic ranging from $79-139 depending on the machine.

I was also told that Atari was/is running some kind of promotion where they will send you a NEW 800XL if you send them $35.00 and and your broken 800 or 400. Does anyone know if this is still true, and if so, is an 800XL what I want? (I already bought a used 400 with 32K so that my daughter can play some games, but a lot of the software that I want to use is 48K only, and therefore useless on the 400).

In summary, I would appreciate any information that you have about my problem and the potential solutions that I've outlined.

Thanks in advance......

481. DOS Detective

Newsgroup: comp.sys.atari.8bit
Date: 1987-08-13 23:51:47 UTC
From: curzon@kaoa01.dec.com
Message-ID: <11438@decwrl.DEC.COM>
Source record: 117535

A while ago I asked how you test which DOS is loaded into memory. I got no answers, but a couple of requests to post an answer if I found one. Here's what seems to work so far.

DOSVEC ($0A) memory location points to what SpartaDOS refers to as COMTAB. ICD has documented its use of COMTAB memory, here are the relevant bytes to test:

1. COMTAB + 0 - jump instruction ($4C)
2. COMTAB + 3 - jump instruction ($4C)
3. COMTAB + 6 - vector (NOT a jump instruction)

Atari DOS's, as well as SuperDOS, SmartDOS, will fail test 1 and 2. Test 3 is necessary because MachDOS passes test 1 and 2; but MachDOS DOES have a jump instruction at COMTAB + 6. SpartaDOS and DOS XL will pass all three tests.

PS:

One of the Sparta COMTAB vectors is to a file crunch routine which returns the next word on the file line in a small buffer in COMTAB. However, this is the usual Atari machine language format, incompatible with Action strings. I did a filename cruncher which returns the filenames in Action strings, if anyone thinks it will save them time send me mail (I don't receive the newsgroup distribution at present). The routine works with SpartaDOS and DOS XL.

482. 1200 baud modem wanted

Newsgroup: comp.sys.atari.8bit
Date: 1987-08-15 01:33:21 UTC
From: tpcharron@watmath.UUCP
Message-ID: <14339@watmath.waterloo.edu>
Source record: 117536

I'm looking to buy a good cheap or used modem for my 8-bit atari. I have an XM-301 modem now, but am tired of waiting for it constantly. Any suggestions are welcome. I KNOW that this question is boring to those users who could care less, so I ask that you e-mail me. Thanks.

Tim Charron
tpcharron@Watmath.waterloo.edu

p.s. I'm going to be in Toronto the start of September, and if anyone in the area has a modem they're willing to sell, give me a call (after Sept. 8). I'm in the phone book.

483. vt52em Documentation

Newsgroup: comp.sys.atari.8bit
Date: 1987-08-16 15:03:21 UTC
From: mark@lakesys.UUCP
Message-ID: <175@lakesys.UUCP>
Source record: 117537

VT52EM Documentation

Vt52em is a vt52 emulator for the Atari 8-bit computers with an RS232 interface and Hayes compatible modem. It was written in ACTION! and compiled with the run-time libraries, therefore the ACTION! cartridge is not necessary to run this program. I am unable to distribute the source code at this time as the code for the 80 column driver is copyrighted.

The program emulates 80 columns by using the Graphics 8 mode. I find the font quite readable, more so than some other 80 column emulations I have seen. To use it I suggest you have either a monochrome monitor or a good B/W TV set. It is all but unreadable on a color set due to artifacting.

The program has been tested on a 130XE using Atari DOS 2.0, 2.5 and SpartDOS 3.2 under both the XE/XL OS and the old 800 OS (version B) loaded in from a Translator disk. If you experience any compatibility problems please let me know.

Vt52em supports a subset of the vt52 terminal capabilities. These include cursor positioning, most of the edit and erase funtions (insert line and delete line, erase to end of line, etc., etc.), and inverse video (standout mode). Some things it does not support are blinking and half-intensity text, graphics mode, and status/25th lines. It also does not support hard tabs or a DEL/Rubout key (ascii 127). These are slated for a future release. IF connected to a Unix/Xenix system do an 'stty -tabs' to have all tabs converted to spaces (soft tabs).

The program also does not include any form of file transfer. I wrote it primarily as a means to use Unix/Xenix programs requiring terminal emulation. Included below is a Unix termcap entry that will supplement the standard vt52 entry and take advantage of the added features of vt52em:

```
a1|atari|atari vt52em:\
:am:al=\EL:dl=\EM:so=\Ep:se=\Eq:tc=vt52:
```

If using an Atari DOS (2.0 or 2.5) you must pre-append the program to an RS232 loader, rename it AUTORUN.SYS, and boot the disk with Basic disabled. With SpartaDOS you may run it from the command line as long as the RS232 handler has already been loaded in.

Using the Program

After booting the program, and passing the title screen, you are placed in a command mode. Typing a '?' followed by RETURN will display a list of all the commands and their usage. Most of the commands should be self explanatory. The program implements control-S/Q flow control to prevent buffer overflow at bauds of 1200 and 2400 (screen writing in Graphics 8 is

SLOW, about 1200 baud max). This feature may be turned off or the start and stop characters may be changed if the system you are on uses different ones.

Pressing <START> when in command mode will put you in Terminal mode.
Pressing <SELECT> when in Terminal mode puts you back in command mode.
Pressing <OPTION> in either mode will flip the screen colors (i.e. from black on white to white on black).

The 'QUIT' command will do a Cold Start (reboot the machine). I will add a more graceful exit in a future release.

The terminal mode supports generation of braces, tilda, and the grave accent. Key presses to generate them are as follows:

(note: CNTL-SHIFT denotes holding both the CONTROL and SHIFT keys down simultaneously while pressing another key)

CNTL-SHIFT t = tilda
CNTL-SHIFT g = grave accent
CNTL-SHIFT [= left brace
CNTL-SHIFT] = right brace

A final note: this program is released into the Public Domain. The author makes no quarentees implied or otherwise. The program may be freely distributed but remains the property of the author. The program may not be sold or in any way exchanged for profit. If any are aware of this happening I would appreciate them notifying me.

I have used a NEC green-screen for a few years. I have no objections to it at all. It cost me $80 used. I frequently use it in 80 column mode as a terminal, and the characters are clear and crisp. The only problem (and I think this is a generic problem with monochrome monitors) is that if the chroma signal is hooked up, so that colors appear as line shading, then the 80 column display is unreadable. With chroma disconnected, there is no distinction between different colors.

Note: the real problem here is that the default background color is blue. If it were black, there would be no problem.

Following are instructions for upgrading a 600XL to 64k. I promised to write this up and post it some time ago. Thanks for giving me another incentive, and apologies to all who have waited for this.

Upgrading an ATARI 600 XL to 64k memory

Hans Breitenlohner
Computer Science Center
University of Maryland

It is fairly simple to upgrade a 600XL computer to 64k memory. Parts required are two 64k by 4 RAM chips (TMS 4464 or equivalent), a 14 pin dip header (optional) and three pieces of hookup wire. Tools required are screwdrivers, pliers, soldering iron, etc. No special tools of any kind are required.

Having said this much, I feel that I should include the following DISCLAIMER: This project requires that you open your computer, and solder and maybe cut traces on the circuit board. If the thought of this makes you uncomfortable, if you have no experience with this kind of work, or don't have access to suitable soldering equipment, then this job is NOT for you! You will definitely void your warranty, and if your computer does not work you will be on your own. You may have problems getting it fixed if the need should arise in the future. (Of course, if you are willing to pay someone 50-60 dollars to fix a 600XL, talk to me, and I would love to help you out!)

No warranty, expressed or implied, including but not limited to ....
If you try this, however, and have problems, send me mail and I will try to help, within the constraints of available resources.

Commercial alternatives: American TV advertises a 64k expansion for the 600XL. I do not know if it is similar to this, or if it is the plug in unit which Atari advertised at one time. Closer to home (for me, anyway) Computer Service Land (14506-B Lee Road, Chantilly, Va., 22021, 703-631-4949) offers an upgrade kit for around 30-40 dollars. I have not seen it, but have been told that it is very similar to what I have. The extra money may buy you better documentation or after-the-fact support.

A. A brief description of the 600XL

The 600XL is a stripped down version of the 800XL. With a few exceptions
the circuitry is the same as in the 800XL. The case and circuit board
are smaller, as a result the layout had to be changed, and things are squeezed
together more tightly. Memory consists of two 16k by 4 chips, and there is
an extra IC in the memory logic (more on that later). There is no video out.
However, all the traces for it seem to be on the circuit board, and if you
remove the channel 2/3 switch, put in a 5-pin DIN socket, and plug in
all the resistors, caps, and transistors, it should be possible to get
the video output just as in the 800XL.
Along with the layout, the numbering of the ICs was changed, and different
sections of multi-section ICs may be used than in the 800XL.

B. Schematics

I used the Sams Computerfacts for the 800XL when I worked this out. They are
not inspired (especially in their use of logic symbols for some of the standard
74LS circuits) but do appear to be complete and correct. I am not aware of
any specific 600XL schematics. I will explain this project so that you
do not need schematics to complete it.

C. The Upgrade

Take apart your computer and remove the shielding from the circuit board. If
you need step by step instructions on which screws to loosen, and when, read
the second paragraph of this again, now, before it is too late.
Two small warnings, though: You can't fold the top of the case to one side
without disconnecting the keyboard cable, as you can on an 800XL. Pull the
small circuit board out of the socket on the main board. I do not think
the cable is meant to be removed from its socket. Secondly, there is one
screw holding the circuit board to the case inside the shield (near the
modulator). It is fairly easy to remove, but requires lots of care when
reassembling.

I have done this project once, and the circuit board had the following
identification (on the bottom):
ATARI INC.
MADE IN HONG KONG
CO61677 7/1983
REV. X9A
If yours is significantly different, your mileage on this project may vary!
The ANTIC chip (u9) should be a CO21697, and not a CO12296. I think all 600XLs
have the correct one.

Replace the two memory chips (u11, u12) with TMS4464 or equivalent. I ordered
mine from Microprocessors Unlimited. I paid less than $12.50 then (about
a year and a half ago), and received them within 2-3 days of ordering.

The address multiplexers, u5 and u6 (74LS158) are not connected to the address
bits A14 and A15. u6 pin 10 and u5-3 are grounded. They need to be connected
to the two address signals. It does not matter which pin is connected to which
of the signals. This may be done by cutting the traces on the
bottom of the board feeding those two pins, or by removing the pins from the
sockets (assuming the board is socketed, mine is). There are four feed-through

holes on the board about halfway between u9-21 and u14-1. The rightmost two are connected to A14 and A15, and I ran wires from there to the two legs of U5 and U6 which I pulled out of their sockets. If you decide to cut traces and do the wiring on the bottom of the board, there may be better ways. A14 is available at the CPU u10-24, the ANTIC chip u9-19, at the second feed through from the right, and at u15-9. A15 is available at u10-25, u9-20, rightmost feed through, and u15-15.

After either of the previous steps you may want to run memory tests. To do this you need to plug in the keyboard and power supply, being careful not to short anything, etc. In either case you should see 16k of good RAM.

There is circuitry in the 600XL to prevent references to RAM above 16k. Half of the 74LS375 (unused in the 800XL) is used to latch A14 and A15. The extra circuit, a 74S32 at u18, combines these (latched A14 at pin 5, latched A15 at pin 4, OR of the two at pin 6), and ORs the original CAS signal (pin 10) with the result (pin 9) to produce the actual CAS signal to the memories. To complete the upgrade, remove the 74S32 from location u18, and either insert a DIP header with a jumper from pin 8 to pin 10, or solder a jumper to the board between the two pins. If you perform this step before the previous two, you will not be able to run memory tests, or use it in any other way.

Reassemble the computer. If you run memory tests now, you should see 40 or 48k of good RAM, depending on whether Basic is enabled. The computer should act exactly like an 800XL in all respects.

P.S.: I have noticed that the picture quality from my 600XL is somewhat worse than from 800XLs. In particular there are six or seven vertical bars near the left edge of the screen, probably related to memory refresh signals. I do not know if that is a problem with 600XLs in general, perhaps caused by the different layout, or if the problem is unique to my system. I also do not recall if the problem was there before I did this upgrade. If anybody does this and can answer either of these questions, please let me know.

P.P.S.: Now that 256k by 4 memories are available at somewhat reasonable prices, the way is open to take one of the 256k upgrades for the 800XL and adapt it to the 600XL.

---

487. Re: Atari 2600 specs/instruction set/programming

Newsgroup: comp.sys.atari.8bit
Date: 1987-08-20 00:44:45 UTC
From: long@sask.UUCP
Message-ID: <823@sask.UUCP>
Source record: 117541

Once upon a time, about 1 yr. ago, someone posted a whole pile of information about the 2600. I believe it contained virtually everything you could want to know about the machine (Ops, wiring, and hints). I had it saved for about 8 months, (for interests' sake) but then decided that realistically, I was never going to look at it again, so I deleted the file.

However, I know it existed once, and therefore, someone must have a copy, even if only the guy who posted it!!

Warren

Message-ID: <870820145709.7.JRD@GRACKLE.SCRC.Symbolics.COM>
Source record: 117542

I've been looking at the little typeahead frob posted by u-jleigh recently. It WON'T work as is with Kermit-65, as was previously alleged, but it can easily be hacked to make it work. However, there are two ways to go here: either load it external to kermit, as the posted version requires, or build it into kermit, and have kermit turn it on at init time, and off at exit time (or maybe make it switchable or something). However, since it hacks on interrupt vectors, it'd be nice if the embedded version could detect the presence of the separately loaded version, and not preempt it.

So, the questions before the house are: 1) Would the listening audience like to see this feature added to kermit, and 2) is there any good place in OS ram for storing facts like "The typeahead handler is already in place, dummy!"?

I for one would not like to see Kermit-65 do any type ahead buffering. I'm using it exclusively. (Hey, just for the record, this is a GREAT program!!! Where can I tell FTD to send the wreath of achievement? Or do you have a local party store that takes Visa & delivers.) SpartaDOS already does wonderful type-ahead buffering.

More importantly, the Atari OS is a great piece of work. Device Independence is an important feature that puts it with today's efforts. In the nature of this work, it is better to make an external load-once type ahead program that works with everything than to lock you into using this Kermit to achieve it. Given a good general purpose modified K:, you could offer typeahead to everything, all the time.

It's this kind of technojunk that keeps my 8bit a competetive tool with the IBM PC I hang on my wall.

Does anyone know the easiest way to contact Keith Ledbetter?

He is the author of my favorite term prog, Express! 1030/xm301. I do not have a CompuSpend account or a GEnie or even delphi accnt. I would like to find out if he uses Bitnet or one of the other major (free) networks.

My main reason is this: I would like to see Exp! converted to 80 col.
Has anyone done this?

I have Omniview...should I just get a copy of Omnicom? Has anyone used Omnicom? Will it support a Hayes compat 1200 baud modem? Does it do up/downloading? What is the general reaction to this piece of software? It is of good quality or is it "just what is available?"

F1.GDM @ ISUMVS.bitnet

Keith is working for ICD Inc, as a programmer, you can write to him in care of ICD or try calling the ICD BBS (I don't have their address or number with me now.)

As far as I know the only networks Keith has access to is Compuserve and GEnie.

I wonder if the new program SX Express!, which Keith is writing for the new SX212 modem supports 80 columns? Any comments Neil???

I have omnicom for the 800, and I have heard of newer versions with more features. At any rate:
1. My copy has no explicit support for "Hayes" compatable modems. (If you want to know why Hayes is in quotes, read the fine print on the outside of a Hayes box. On the other hand, I can type atds pretty quickly.

2. It does kermit file transfers.

3. It is ok, but would be improved if: all ascii characters were correct (curly braces and such are displayed as the corresponding atascii graphics character), if the screen didn't permanently change colors when you do file transfers, and if you didn't have to refer to the 850 manual for special numbers when setting it to 2400 baud. I'll give it a better than "just what's available" but not really a polished product rating. Incidentally, until recently I used it extensively as a terminal, and it worked fine with vi and Gnu emacs (although I did have to put in a termcap with delays on reverse scroll to use it with emacs at 2400 baud).

Here are two brief followups to my recent posting:

1. Feel free to pass the article to any bulletin board, network, newsletter, etc.

2. If you install any 600XL upgrade which uses 64k by 4 RAMs, you should be aware that these are 256k RAM technology. 256k RAMs are much more forgiving about refresh than 64k RAMs. While this is generally a good thing, it causes problems with the way the XL distinguishes between cold start and warm start. Especially when the machine is cold, you may have to power it down for 10-15 seconds to convince it to do a cold start. There was a posting of a ROM patch to force cold starts from the keyboard, and I have developed something similar (better, of course, IMHO :-). Let me know if you want either.

Interview with Kieth Ledbetter about the new Express! BBS Professional

Network: Atari and the Hard Disk User Group have recently had the distinct pleasure of interviewing Keith Ledbetter Author of the highly successful Express! series of Terminal and BBS Programs. This interview centers on the newest of his BBS programs:

BBS Express! Professional

Chuck: Welcome Keith and we are honored to have this opportunity to talk with you about you current efforts.

Keith: Thank you Chuck. It's nice to have support like yours.

Chuck: Believe me Keith there are hundreds more that support your work. I'm not alone. Well I have a pretty exhaustive list of questions about your newest version of BBS Express! and I'm sure the readers will be glad to hear about it.

Let me start out by asking one of the most frequently asked questions I get here. Will you allow other SysOps and programmers the opportunity to write their own files as utilities games and other things for this version?

Keith: Absolutely. This new version is dramatically different than all the others. I'll supply a list of equates for those wishing to write nice utilities for the BBS. There will also be some example programs. some source code will be on the disk

All the system vectors and variable names that point to commonly used routines will be supplied so that the bulk of utilities folks write that utilize SpartaDOS [3.2d] functions will be easier to write. You don't ha ve to write all that stuff now just use the routines already provided while writing your program around them.

Things like input/output from/to the modem etc. will be user accessible for people who want to write their own external commands.

Chuck: Which language did you use to write the new version?

Keith: Well I used my own ST and a cross assembler and ported over to the 8-Bit Atari system.

Chuck: Then which language do the programmers use to add these other options?

Keith: MAC/65 or any other machine language as long as the addressing corresponds to the correct vectors I'll supply. Probably MAC/65 will be the best for this. Anybody having experience in ML can write files for the BBS. It's real simple. Real easy for folks to write their own commands.

Chuck: What are some of the new things we can expect...Changes in format etc.?

Keith: Well you are really going to need a ramdisk or a hard disk to run this version. Most of the commands are external commands [separate files] and using a floppy will be slow to say the least. It can be done but will be very slow. You might be able to get by with a US Doubled 1050 but you're still talking about accessing the drive for every command.

You get to basically use the commands supplied and if you don't like those you can write your own. It's a real simple task.

Chuck: Whew! Let's jump ahead for a second and let me ask when this gem will be up for sale.

Keith: Oh that's really hard to say. Right now I'd say...

Chuck: ...Before this newsletter hits the stands in October???

Keith: No. right now I'd say it's about 80% complete. I'm hoping to get into Beta test by the end of this month [August] and it might be possible by October but it's really hard to say. I'll let Network: Atari and the Mouse BBS do the Beta testing.

Chuck: Music to my ears....

Keith: I figured it would be.

Chuck: OK back to configuration. I had one of my users ask if you were going to support Kermit Protocol.

Keith: No we'll support XMODEM CRC and YMODEM but not Kermit.

Chuck: You mentioned SpartaDOS 3.2d and I was wondering which other DOS's can be used.

Keith: The new system absolutely requires SpartaDOS 3.2d. No other DOS. You can use the R-TIME8 or run off of the internal software clock in SpartadOS.

Chuck: What about the Sparta-X Cartridge?

Kei th: It's being worked on right now. It should work with that because we are going to try to preserve all of the system vectors all the time/date vectors and all of that.

Chuck: Are there any forseeable problems running off of an MIO or P: R: Connection?

Keith: No I'm running it off of an MIO right now. Should be no problems at all.

Chuck: Ok how many columns support are we to expect? 38? 40? 80?

Keith: There are basically 4 sets of menus under HELP40 and HELP80 Pathnames. Support for the ST for sure and maybe VT-52. I'm still thinking about the VT-52 though. We'll see about that one. It's possible but I'm not sure at the moment.

Chuck: What about the high baud rate? What's the limit this time?

Keith: 300 through 9600 Baud.

Chuck: Will it actually do 9600?

Keith: Yes but you have to have the exact same type of modem on each end to have it work. There's not much call for it but it's there.

Chuck: I figure there's only 2 other folks out there in modem land pushing 9600 at any rate so I'm sure we don't really need it. I'm not going to go out to buy 9600 unless it becomes standard.

Keith: Right but it's in there for those that want it.

Chuck: Basically 2400 baud max will be used. Great.

Keith: Right.

Chuck: Ok What else?

Keith: Well before I let the SysOp define his/her own pathnames and such but this version has them all Hard-Coded.

You have to CREDIR each of those since they are hard-coded. All of the Sub-Directories have been set up the same. Hard-Coded. There are COMMANDS> HELP40> HELP80> BASES> USERLOG> FILES> and other subs that need creation. Also the Message Bases 32 of them are Hard-Coded. BASE01 BASE02 etc.

4000 Bytes maximum P/Message and 250 Messages P/Base. Plenty to go around I guess. That's roughly 50 lines @ 80 Columns P/Line. A short novel.

Chuck: That should make everyone happy. Is there a good Message Base Editor?

Keith: Absolutely but it's set up a bit different. Previously we had all those commands before you entered the Base but now the sub-commands come after that. I found it was easier that way.

Chuck: How about the Menu's? Will they be set-up the same? Can I use my old menu's from the old system?

Keith: No because they are set-up a little different however I may write a quick converter program to change all those over. Maybe even one for the userlog.

Chuck: Are the "letter-commands" still going to be the same?

Keith: Sure but there may be "word" command support too. The way it is now and the way it'll probably enter Beta test will be with the letter options.

Chuck: Ok. What did I forget?

Keith: You have to ask me about download files!!!

Chuck: Hehe..ok hey Keith what have you done about the 8 Pathname limit in the download section?

Keith: Well I'm glad you asked me about that. There are now 516 128 available filenames that you can have in your Massive download section!

It's set up like this: I have Hard-Coded the program to read sub-director ies FILES_01> through FILES_32>. Under each of those sub-directories are all the sub-directories that you want scanned. Figure 127 SysOp-Chosen Sub-directories under each of these FILES_xx> sub-directories and each containing 127 downloadable files you come up with the big picture.

Another way to put it is you can have sub-directories FILES_01> through FILES_32> each containing 127 sub-directories apiece and each of those containing 127 files.

Chuck: Alright! You shouldn't have any more complaints about that!

Keith: Nope. I took care of that one for a while.

Chuck: That was probably your biggest complaint true?

Keith: Yeah that was the big one. The people that have switched to the other BBS switched because of that problem. Well now we've made the whole BBS better so I expect most of those to come back.

Chuck: I hate to admit it Keith but I was one of those that switched. I'm so ashamed. But now that we have a new toy I'll gladly switch over again to see the changes you've made. I really have to say that personally I don't care which BBS I operate but it has to suit the system I run. With 120 Meg to play with I need flexibility.

Keith: Gotta do what you gotta do.

Chuck: Sigh.

Keith: Getting back to the Downloads. Each file on the system will have a 240 character description space allotted to it just like the ST Express! BBS.

Chuck: That also takes up disk space. I can see why you need a large system.

Keith: Yes I figure everyone will go with double density and that'S why I went with 240. Each will only take up 2 sectors on the disk P/Description. But that is at the SysOps approval. If you don't want to use the descriptions you can set that up in the SYSDATA.DAT

file.

Chuck: Does it have a catalog command? Like the ST version?

Keith: Better than the ST version. It will allow a catalog of the files you specify with wildcards. There will be 15 names P/Page and each one downloadable with the press of a single key.

Chuck: That sounds like it's going to take some dedicated effort by a SysOp to set it up. But once it is done you can have a class act.

Keith: Sure. And all the file descriptions are editable from the SysOp but really all you'll have to do to set it up is just to copy all your files over and then go through and do a rowse. It will tell you "Description not available" and you just hit dit to write up a short description. It's only a lot of work if you have a lot of files like you.

Chuck: I'm having typer's cramps already. However it costs to be the boss so I can't complain.

On to another subject. How about the logon data. will that still be setup the same? Selectable to go either to the printer or a disk file?

Keith: Yes it's the same as the older versions. You'll be able to use handles and such and the initial logon sequence asks quite a lot of questions so if it goes to a disk file it will take up a bit of space. You have plenty. The rest is similar to the other versions.

Chuck: Does that include download ratio's?

Keith: Yes. It saves all that data to the logfile.

Chuck: What are you going to charge for this?

Keith: I'm n ot really sure yet. It won't be much though.

Chuck: Ok what's the maximum number of active users we can have?

Keith: Well over 65 000 but Realistically you have a logical limit. See SpartaDOS can handle a single file 8 Megabytes in length. Take that number of bytes and divide it by 256 bytes [the number of bytes each userlog takes up] and you come out with around 30 000 or so.

Chuck: Well I don't think that anyone will have that many user. Even Atari Base would find it tough.

Keith: Right and that would be almost a whole Hard Drive partition just for the userlog.

Chuck: Time to buy a mainframe!

Keith: Yeah no kidding.

Chuck: What about Passwords?

Keith: On this new version the passwords are user supplied.

Chuck: Great. How many characters?

Keith: From 1 to 15 characters I believe. Again though just like the ST version...the user will be assigned a record number and if they logon with that number then the look-up time will be almost immediate.

Now they can optionally key in their Handle along with their password and then the board will search for it much like it does when you send E-Mail to somebody. It looks to see that they exist. So there are multiple ways to logon.

Chuck: Ok would you please explain again if you will the equate functions that you're supplying with the disk?

Keith: Sure. Really there's 2 sets of equates. One is the MAC/65 source code equates to all of the "Global Variables" including the SYSDATA data the USER record data Current date current time and whatever. Then there are also a set of vectors that are jump vectors. These help you control data within the program itself.

[ZNOTE: An indepth description was given concerning these equates but this will come on the disk so we won't waste the space here going into detail.]

Chuck: Then any Atari assembler will be functional for these mods.

Keith: Correct. Yes. It's all very simple because most of the data you need is already in the shell of the program. You don't have to come up with a lot of the user input. It's already there.

Even when you're talking about really indepth utilities or games like adventures and such those things are readily accessible.

Chuck: Then are we limited to the size of these external commands?

Keith: Yes. Somewhere around 16K is the limit. That's even bigger than SpartaDOS itself so those are really involved. The shell really takes all the kluge work out of writing an assembler program. It's totally possible to write a game like Zork(tm) for on-line use if that's what you wanted to do.

Chuck: Where can the folks purchase the p rogram?

Keith: This will be through Orion Micro Systems as always. The main support/sales board will remain there.

Chuck: Can the Hard Disk User Group members get a special price on it?

Keith: I'm sure we can work something out for your members. T hose are probably the people most likely to purchase it. Sure.

Chuck: Ok I'll send Chris King at Orion a list of my members.

Keith: That'll do it.

Chuck: Next question. How many security levels are allowed on the new system?

Keith: About 320. See there are 32 Msg Bases 32 File areas [SIGS] and 32 command levels. So basically each user record has 32 flags for each of those things. Then there are other things that you would need to read the documentation to see.

Chuck: Is there an option on the new board to allow survey's?

Keith: Yes. Up to 32 trackable surveys with an un limited number of questions.

Chuck: Unlimited?

Keith: Well by disk space only.

Chuck: Superior!

Keith: Again we're talking about a BBS designed for a really big system. So by now you can probably see that this is really for a Hard Disk configuration.

Chuck: I was seriously hoping for these kinds of modifications and trvthfully there are a lot of folks going to hard disk systems. Therefore this is quite a marketable product in that sense.

Keith: Right. You can still run it from floppy but you'll be severely limited in the options allowed. Even with the use of a ramdisk.

Chuck: I see. Those folks running Megabytes and larger RAMdisks will be able to apply most of the available options.

Keith: Correct.

Chuck: Ok here's one. I know this is an important issue. Are the folks that have purchased the other express! programs going to be able to trade in their old versions for the new one?

Keith: Yes they can. Trading in the master disk for a replacement. Even tho ugh this version is being called BBS Express! Professional [Express! PRO] it is a version 2.0 upgrade of the 850 version. So those that are currently owners will be able to upgrade it for a fee that has not been set yet.

There is also going to be a 1030 version of BBS Express! Professional so that news should make everyone happy. This will be released sometime after the 850 version.

Originally we were not going to write a 1030 version. We figured hey...if you want to keep up with us you should upgrade to an 850 but we figured hey...it was really the 1030's that got us started so we'll support them too.

Chuck: I'm not sure how many folks run 1030's and Hard Drives but it's there if needed.

Keith: Right. It has now gotten to the point now where we're going to have to talk to the folks a little more now to determine what kind of system they want. We have to be sure they get the version that they can use best. With so many version out it may confuse a few.

Chuck: To be sure they don't get a Hard Disk version to run off a single drive...etc.

Keith: Right.

Chuck: Hey! Do you know what just happened?

Keith: What's that.

Chuck: I just ran out of questions!

Keith: Ha!!

Chuck: Well I sure do appreciate all this good information and I'm sure my readers do too.

So now's your chance to ramble and tell the folks what I've neglected to ask.

Keith: Well the most important thing to get across is that this is really a large system BBS program and it really does act that way.

There's 5 different logon sequences that the SysOp can use. There are a LOT of one-key commands available for the SysOp. See this version is different in that it was written more for the SysOps editability and still allows more things for the users. It's simply a better all-around program.

The nice part about it is the fact that it's what the SysOp wants.

A lot of the program isn't even written yet and I'm not really sure which way i want to go on some of the things. Sorta flying by the seat of my pants. That's why I needed some suggestions from your users. I've basically added all the features that everyone has asked for.

Chuck: Well...ending an interview especially this one is a hard thing to do but I suppose we have to do it.

Keith: Ok well let's do this... give me a call in a few minutes. I'll boot up the new version and let you take a look at what I've got completed. This way you can get a general idea of the new system.

Chuck: I'm shakin' all over! Ok and I want to thank you VERY much for this exclusive interview today!

Keith: My pleasure. No problem.

Chuck: Fantastic. Take care Keith.

Keith: See you later.

[ZNOTE: I called Keith and saw the new version a t work. I want one! I figure with all the changes that he has made it will be worth whatever he asks for it. And the option to trade in your old master for the new version is a great deal!

Plan to call Network: Atari HD Express! BBS in the next few weeks to see this version at work!

I will guarantee you wil l be impressed with his efforts and continue to support him in his endeavors.

And last but certainly not least Keith... You've done it again!

495. new express bbs trailer

somewhere out there is a file i sent to info-atari8. it concerns an interview of Keith Ledbetter by Chuck Leazott of ZBBS in San Antonio TX about Keiths new EXPRESS BBS Professional. The transcript is due to be released in the Hard drive Users Group (run by Chuck Leazott) newsletter. Since most people probably dont belong to that users group, I have put it on this network as a public service. Replies and questions can be directed to me, and I will forward them on to Chuck. Chuck runs a BBS, but I do not have his number handy on this terminal...If you are interested, send me a mail-gram and I will copy out the info to you. I can remember that his bbs is ZBBS in the above mentioned location. it has a 1 Meg MIO and 1 or 2 Hard disk...I think 120 Meg total...and its a 130xe...thats all I remember.. oh yah...300/1200/2400. 498. ACTION! vs. 850 handler

Newsgroup: comp.sys.atari.8bit
Date: 1987-08-23 21:23:19 UTC
From: ehs@jumbo.dec.com
Message-ID: <903@jumbo.dec.com>
Source record: 117552

I am trying to turn a compiled ACTION! program into an AUTORUN.SYS file. It needs the R: handlers that are downloaded from the 850. When I use the standard AUTORUN.SYS file to load these handlers, then compile and run the program, everything is ok.

When I save the compiled program, using the ACTION! monitor's WRITE command, and append the binary to the standard AUTORUN.SYS, I get a file that doesn't seem to work. Immediately after loading it from DOS, I get a garbage screen and the keyboard locks up.

Since I have been able to save and run other ACTION! binaries that don't need these handlers, I tried dumping the downloader, disassembling it to verify that it looked relatively innocuous, and embedding it into my ACTION! program as a ML insert. This seems to work fine when I compile and run from memory, without needing the old AUTORUN.SYS file, but the saved binary does not seem to work any better.

I vaguely recall some discussion in this newsgroup of some sort of bad interaction between ACTION! binaries and the 850 handlers. Can anyone explain the problem and/or suggest a workaround.

Much thanks for any help.

Subject: Keyboard Buffer for Kermit 65
To: info-atari8@score.stanford.edu

I have been told by John Dunning that his Kermit 65 uses page 6
of memory as a buffer and it so happens that the keyboard buffer also
resides in page 6. Why it still works remains a mystery.
In any case, I caution using the keyboard buffer in Kermit 65 until John
has installed it in a safe location in his new version of Kermit 65.
You may still of course use the keyboard buffer for other programs that
don't use page 6.

Following are instructions for upgrading a 600XL to 64k. I promised to write
this up and post it some time ago. Thanks for giving me another incentive,
and apologies to all who have waited for this.

Upgrading an ATARI 600 XL to 64k memory

Hans Breitenlohner
Computer Science Center
University of Maryland

It is fairly simple to upgrade a 600XL computer to 64k memory. Parts required
are two 64k by 4 RAM chips (TMS 4464 or equivalent), a 14 pin dip header
(optional) and three pieces of hookup wire. Tools required are screwdrivers,
pliers, soldering iron, etc. No special tools of any kind are required.

Having said this much, I feel that I should include the following DISCLAIMER:
This project requires that you open your computer, and solder and maybe cut
traces on the circuit board. If the thought of this makes you uncomfortable,
if you have no experience with this kind of work, or don't have access to
suitable soldering equipment, then this job is NOT for you! You will
definitely void your warranty, and if your computer does not work you will be
on your own. You may have problems getting it fixed if the need should arise
in the future. (Of course, if you are willing to pay someone 50-60 dollars
to fix a 600XL, talk to me, and I would love to help you out!)

No warranty, expressed or implied, including but not limited to ....
If you try this, however, and have problems, send me mail and I will try to
help, within the constraints of available resources.

Commercial alternatives: American TV advertises a 64k expansion for the
600XL. I do not know if it is similar to this, or if it is the plug in unit
which Atari advertised at one time. Closer to home (for me, anyway) Computer

Service Land (14506-B Lee Road, Chantilly, Va., 22021, 703-631-4949)
offers an upgrade kit for around 30-40 dollars. I have not seen it, but have
been told that it is very similar to what I have. The extra money may buy
you better documentation or after-the-fact support.

A. A brief description of the 600XL

The 600XL is a stripped down version of the 800XL. With a few exceptions
the circuitry is the same as in the 800XL. The case and circuit board
are smaller, as a result the layout had to be changed, and things are squeezed
together more tightly. Memory consists of two 16k by 4 chips, and there is
an extra IC in the memory logic (more on that later). There is no video out.
However, all the traces for it seem to be on the circuit board, and if you
remove the channel 2/3 switch, put in a 5-pin DIN socket, and plug in
all the resistors, caps, and transistors, it should be possible to get
the video output just as in the 800XL.
Along with the layout, the numbering of the ICs was changed, and different
sections of multi-section ICs may be used than in the 800XL.

B. Schematics

I used the Sams Computerfacts for the 800XL when I worked this out. They are
not inspired (especially in their use of logic symbols for some of the standard
74LS circuits) but do appear to be complete and correct. I am not aware of
any specific 600XL schematics. I will explain this project so that you
do not need schematics to complete it.

C. The Upgrade

Take apart your computer and remove the shielding from the circuit board. If
you need step by step instructions on which screws to loosen, and when, read
the second paragraph of this again, now, before it is too late.
Two small warnings, though: You can't fold the top of the case to one side
without disconnecting the keyboard cable, as you can on an 800XL. Pull the
small circuit board out of the socket on the main board. I do not think
the cable is meant to be removed from its socket. Secondly, there is one
screw holding the circuit board to the case inside the shield (near the
modulator). It is fairly easy to remove, but requires lots of care when
reassembling.

I have done this project once, and the circuit board had the following
identification (on the bottom):
ATARI INC.
MADE IN HONG KONG
CO61677 7/1983
REV. X9A
If yours is significantly different, your mileage on this project may vary!
The ANTIC chip (u9) should be a CO21697, and not a CO12296. I think all 600XLs
have the correct one.

Replace the two memory chips (u11, u12) with TMS4464 or equivalent. I ordered
mine from Microprocessors Unlimited. I paid less than $12.50 then (about
a year and a half ago), and received them within 2-3 days of ordering.

The address multiplexers, u5 and u6 (74LS158) are not connected to the address bits A14 and A15. u6 pin 10 and u5-3 are grounded. They need to be connected to the two address signals. It does not matter which pin is connected to which of the signals. This may be done by cutting the traces on the bottom of the board feeding those two pins, or by removing the pins from the sockets (assuming the board is socketed, mine is). There are four feed-through holes on the board about halfway between u9-21 and u14-1. The rightmost two are connected to A14 and A15, and I ran wires from there to the two legs of U5 and U6 which I pulled out of their sockets. If you decide to cut traces and do the wiring on the bottom of the board, there may be better ways. A14 is available at the CPU u10-24, the ANTIC chip u9-19, at the second feed through from the right, and at u15-9. A15 is available at u10-25, u9-20, rightmost feed through, and u15-15.

After either of the previous steps you may want to run memory tests. To do this you need to plug in the keyboard and power supply, being careful not to short anything, etc. In either case you should see 16k of good RAM.

There is circuitry in the 600XL to prevent references to RAM above 16k. Half of the 74LS375 (unused in the 800XL) is used to latch A14 and A15. The extra circuit, a 74S32 at u18, combines these (latched A14 at pin 5, latched A15 at pin 4, OR of the two at pin 6), and ORs the original CAS signal (pin 10) with the result (pin 9) to produce the actual CAS signal to the memories. To complete the upgrade, remove the 74S32 from location u18, and either insert a DIP header with a jumper from pin 8 to pin 10, or solder a jumper to the board between the two pins. If you perform this step before the previous two, you will not be able to run memory tests, or use it in any other way.

Reassemble the computer. If you run memory tests now, you should see 40 or 48k of good RAM, depending on whether Basic is enabled. The computer should act exactly like an 800XL in all respects.

P.S.: I have noticed that the picture quality from my 600XL is somewhat worse than from 800XLs. In particular there are six or seven vertical bars near the left edge of the screen, probably related to memory refresh signals. I do not know if that is a problem with 600XLs in general, perhaps caused by the different layout, or if the problem is unique to my system. I also do not recall if the problem was there before I did this upgrade. If anybody does this and can answer either of these questions, please let me know.

P.P.S.: Now that 256k by 4 memories are available at somewhat reasonable prices, the way is open to take one of the 256k upgrades for the 800XL and adapt it to the 600XL.

Subject: More wierd questions...
To: Info-Atari8@SCORE.STANFORD.EDU

I've been looking at the little typeahead frob posted by u-jleigh recently. It WON'T work as is with Kermit-65, as was previously

alleged, but it can easily be hacked to make it work. However, there
are two ways to go here: either load it external to kermit, as the
posted version requires, or build it into kermit, and have kermit turn
it on at init time, and off at exit time (or maybe make it switchable or
something). However, since it hacks on interrupt vectors, it'd be nice
if the embedded version could detect the presence of the separately
loaded version, and not preempt it.

So, the questions before the house are: 1) Would the listening audience
like to see this feature added to kermit, and 2) is there any good place
in OS ram for storing facts like "The typeahead handler is already
in place, dummy!"?

What serial driver are you using? John relocates the RS-232 buffer into
page 6 via XIO call, not all drivers support that (they just ignore it).

>In any case, I caution using the keyboard buffer in Kermit 65 until John
>has installed it in a safe location in his new version of Kermit 65.
>You may still of course use the keyboard buffer for other programs that
>don't use page 6.
I use it with the SpartaDOS buffer without problems.
However, the posted version has a bug in the download protocol in binary
mode. John is working on a new version.
SpartaDOS does not support EOF LOOKAHEAD error 3, uploads will result in a
null byte appended. He will fix that also.

This is the best VT100 emulator yet (even if I would like to see some of
the keypad emulation key choices changed - users are never happy :-)).

Thanks, John!

Does anyone know the easiest way to contact Keith Ledbetter?

He is the author of my favorite term prog, Express! 1030/xm301. I do not have a CompuSpend account or a GEnie or even delphi accnt. I would like to find out if he uses Bitnet or one of the other major (free) networks.

My main reason is this: I would like to see Exp! converted to 80 col.
Has anyone done this?

I have Omniview...should I just get a copy of Omnicom? Has anyone used Omnicom? Will it support a Hayes compat 1200 baud modem? Does it do up/downloading? What is the general reaction to this piece of software? It is of good quality or is it "just what is available?"

F1.GDM @ ISUMVS.bitnet

Subject: Re: More wierd questions...
To: info-atari8@score.stanford.edu

I for one would not like to see Kermit-65 do any type ahead buffering. I'm using it exclusively. (Hey, just for the record, this is a GREAT program!!! Where can I tell FTD to send the wreath of achievement? Or do you have a local party store that takes Visa & delivers.) SpartaDOS already does wonderful type-ahead buffering.

More importantly, the Atari OS is a great piece of work. Device Independence is an important feature that puts it with today's efforts. In the nature of this work, it is better to make an external load-once type ahead program that works with everything than to lock you into using this Kermit to achieve it. Given a good general purpose modified K:, you could offer typeahead to everything, all the time.

It's this kind of technojunk that keeps my 8bit a competetive tool with the IBM PC I hang on my wall.

Subject: Re: Atari 2600 specs/instruction set/programming

To: info-atari8@score.stanford.edu

Once upon a time, about 1 yr. ago, someone posted a whole pile of
information about the 2600. I believe it contained virtually
everything you could want to know about the machine (Ops, wiring,
and hints). I had it saved for about 8 months, (for interests' sake)
but then decided that realistically, I was never going to look at it
again, so I deleted the file.

However, I know it existed once, and therefore, someone must have a
copy, even if only the guy who posted it!!

Warren

Keith is working for ICD Inc, as a programmer, you can write to him in
care of ICD or try calling the ICD BBS (I don't have their address or
number with me now.)

As far as I know the only networks Keith has access to is Compuserve
and GEnie.

I wonder if the new program SX Express!, which Keith is writing for
the new SX212 modem supports 80 columns? Any comments Neil???

I have omnicom for the 800, and I have heard of newer versions with more features. At any rate:
1. My copy has no explicit support for "Hayes" compatable modems. (If you want to know why Hayes is in quotes, read the fine print on the outside of a Hayes box. On the other hand, I can type atds pretty quickly.

2. It does kermit file transfers.

3. It is ok, but would be improved if: all ascii characters were correct (curly braces and such are displayed as the corresponding atascii graphics character), if the screen didn't permanently change colors when you do file transfers, and if you didn't have to refer to the 850 manual for special numbers when setting it to 2400 baud. I'll give it a better than "just what's available" but not really a polished product rating. Incidentally, until recently I used it extensively as a terminal, and it worked fine with vi and Gnu emacs (although I did have to put in a termcap with delays on reverse scroll to use it with emacs at 2400 baud).

To: info-atari8@score.stanford.edu

Here are two brief followups to my recent posting:

1. Feel free to pass the article to any bulletin board, network, newsletter, etc.

2. If you install any 600XL upgrade which uses 64k by 4 RAMs, you should be aware that these are 256k RAM technology. 256k RAMs are much more forgiving about refresh than 64k RAMs. While this is generally a good thing, it causes problems with the way the XL distinguishes between cold start and warm start. Especially when the machine is cold, you may have to power it down for 10-15 seconds to convince it to do a cold start. There was a posting of a ROM patch to force cold starts from the keyboard, and I have developed something similar (better, of course, IMHO :-). Let me know if you want either.

For more info, I can be reached in the following ways:

The less than useful graphics characters may be corrected in later releases of OMNIVIEW. I still have the old ROM in my system but I understand that the new one supports tilde and curly braces.

Re: Hayes modem support. I have found it extremely convenient to use the OmniCom keypad editing features to program the numeral keys to send ATDT plus my favorite phone numbers. With CTRL-numeral and SHIFT/CTRL numeral, that is TWENTY possible pre-programmed autodial keys, or ten autodial keys and ten special function keys. A strip of white correction tape can be pasted across the top of the keyboard, just above the numeral keys, to remind you what the CTRL- and SHIFT/CTRL- versions of the keys do. In addition, the sequence gets displayed by Hayes modem local echo in command mode so you can see what number you are dialing.

Fred Sullivan's comments on shortcomings of OmniCom should be forwarded to David Young of CDY, as David has been extremely helpful in correcting bugs and adding useful new features when they are pointed out to him. I am sure David will want to provide excellent support to 2400-baud users and will welcome comments on the problems experienced by the few who are lucky enough to already have 2400-baud modems.

Interview with Kieth Ledbetter about the new Express! BBS Professional

Network: Atari and the Hard Disk User Group have recently had the
distinct pleasure of interviewing Keith Ledbetter Author of the highly
successful Express! series of Terminal and BBS Programs. This interview
centers on the newest of his BBS programs:

BBS Express! Professional

Chuck: Welcome Keith and we are honored to have this opportunity
to talk with you about you current efforts.

Keith: Thank you Chuck. It's nice to have support like yours.
```

Chuck: Believe me Keith there are hundreds more that support your work. I'm not alone. Well I have a pretty exhaustive list of questions about your newest version of BBS Express! and I'm sure the readers will be glad to hear about it.

Let me start out by asking one of the most frequently asked questions I get here. Will you allow other SysOps and programmers the opportunity to write their own files as utilities games and other things for this version?

Keith: Absolutely. This new version is dramatically different than all the others. I'll supply a list of equates for those wishing to write nice utilities for the BBS. There will also be some example programs. some source code will be on the disk

All the system vectors and variable names that point to commonly used routines will be supplied so that the bulk of utilities folks write that utilize SpartaDOS [3.2d] functions will be easier to write. You don't ha ve to write all that stuff now just use the routines already provided while writing your program around them.

Things like input/output from/to the modem etc. will be user accessible for people who want to write their own external commands.

Chuck: Which language did you use to write the new version?

Keith: Well I used my own ST and a cross assembler and ported over to the 8-Bit Atari system.

Chuck: Then which language do the programmers use to add these other options?

Keith: MAC/65 or any other machine language as long as the addressing corresponds to the correct vectors I'll supply. Probably MAC/65 will be the best for this. Anybody having experience in ML can write files for the BBS. It's real simple. Real easy for folks to write their own commands.

Chuck: What are some of the new things we can expect...Changes in format etc.?

Keith: Well you are really going to need a ramdisk or a hard disk to run this version. Most of the commands are external commands [separate files] and using a floppy will be slow to say the least. It can be done but will be very slow. You might be able to get by with a US Doubled 1050 but you're still talking about accessing the drive for every command.

You get to basically use the commands supplied and if you don't like those you can write your own. It's a real simple task.

Chuck: Whew! Let's jump ahead for a second and let me ask when this gem will be up for sale.

Keith: Oh that's really hard to say. Right now I'd say...

Chuck: ...Before this newsletter hits the stands in October???

Keith: No. right now I'd say it's about 80% complete. I'm hoping to get into Beta test by the end of this month [August] and it might be possible by October but it's really hard to say. I'll let Network: Atari and the Mouse BBS do the Beta testing.

Chuck: Music to my ears....

Keith: I figured it would be.

Chuck: OK back to configuration. I had one of my users ask if you were going to support Kermit Protocol.

Keith: No we'll support XMODEM CRC and YMODEM but not Kermit.

Chuck: You mentioned SpartaDOS 3.2d and I was wondering which other DOS's can be used.

Keith: The new system absolutely requires SpartaDOS 3.2d. No other DOS. You can use the R-TIME8 or run off of the internal software clock in SpartadOS.

Chuck: What about the Sparta-X Cartridge?

Kei th: It's being worked on right now. It should work with that because we are going to try to preserve all of the system vectors all the time/date vectors and all of that.

Chuck: Are there any forseeable problems running off of an MIO or P: R: Connection?

Keith: No I'm running it off of an MIO right now. Should be no problems at all.

Chuck: Ok how many columns support are we to expect? 38? 40? 80?

Keith: There are basically 4 sets of menus under HELP40 and HELP80 Pathnames. Support for the ST for sure and maybe VT-52. I'm still thinking about the VT-52 though. We'll see about that one. It's possible but I'm not sure at the moment.

Chuck: What about the high baud rate? What's the limit this time?

Keith: 300 through 9600 Baud.

Chuck: Will it actually do 9600?

Keith: Yes but you have to have the exact same type of modem on each end to have it work. There's not much call for it but it's there.

Chuck: I figure there's only 2 other folks out there in modem land pushing 9600 at any rate so I'm sure we don't really need it. I'm not going to go out to buy 9600 unless it becomes standard.

Keith: Right but it's in there for those that want it.

Chuck: Basically 2400 baud max will be used. Great.

Keith: Right.

Chuck: Ok What else?

Keith: Well before I let the SysOp define his/her own pathnames and
such but this version has them all Hard-Coded.

You have to CREDIR each of those since they are hard-coded. All
of the Sub-Directories have been set up the same. Hard-Coded. There
are COMMANDS> HELP40> HELP80> BASES> USERLOG> FILES> and other subs that
need creation. Also the Message Bases 32 of them are Hard-Coded. BASE01 BASE02
etc.

4000 Bytes maximum P/Message and 250 Messages P/Base. Plenty to
go around I guess. That's roughly 50 lines @ 80 Columns P/Line.
A short novel.

Chuck: That should make everyone happy. Is there a good Message
Base Editor?

Keith: Absolutely but it's set up a bit different. Previously we
had all those commands before you entered the Base but now the sub-commands
come after that. I found it was easier that way.

Chuck: How about the Menu's? Will they be set-up the same? Can
I use my old menu's from the old system?

Keith: No because they are set-up a little different however I may
write a quick converter program to change all those over. Maybe
even one for the userlog.

Chuck: Are the "letter-commands" still going to be the same?

Keith: Sure but there may be "word" command support too. The way
it is now and the way it'll probably enter Beta test will be with
the letter options.

Chuck: Ok. What did I forget?

Keith: You have to ask me about download files!!!

Chuck: Hehe..ok hey Keith what have you done about the 8 Pathname
limit in the download section?

Keith: Well I'm glad you asked me about that. There are now 516 128
available filenames that you can have in your Massive download section!

It's set up like this: I have Hard-Coded the program to read sub-director
ies FILES_01> through FILES_32>. Under each of those sub-directories
are all the sub-directories that you want scanned. Figure 127 SysOp-Chosen
Sub-directories under each of these FILES_xx> sub-directories and
each containing 127 downloadable files you come up with the big picture.

Another way to put it is you can have sub-directories FILES_01>
through FILES_32> each containing 127 sub-directories apiece and each

of those containing 127 files.

Chuck: Alright! You shouldn't have any more complaints about that!

Keith: Nope. I took care of that one for a while.

Chuck: That was probably your biggest complaint true?

Keith: Yeah that was the big one. The people that have switched to the other BBS switched because of that problem. Well now we've made the whole BBS better so I expect most of those to come back.

Chuck: I hate to admit it Keith but I was one of those that switched. I'm so ashamed. But now that we have a new toy I'll gladly switch over again to see the changes you've made. I really have to say that personally I don't care which BBS I operate but it has to suit the system I run. With 120 Meg to play with I need flexibility.

Keith: Gotta do what you gotta do.

Chuck: Sigh.

Keith: Getting back to the Downloads. Each file on the system will have a 240 character description space allotted to it just like the ST Express! BBS.

Chuck: That also takes up disk space. I can see why you need a large system.

Keith: Yes I figure everyone will go with double density and that'S why I went with 240. Each will only take up 2 sectors on the disk P/Description. But that is at the SysOps approval. If you don't want to use the descriptions you can set that up in the SYSDATA.DAT file.

Chuck: Does it have a catalog command? Like the ST version?

Keith: Better than the ST version. It will allow a catalog of the files you specify with wildcards. There will be 15 names P/Page and each one downloadable with the press of a single key.

Chuck: That sounds like it's going to take some dedicated effort by a SysOp to set it up. But once it is done you can have a class act.

Keith: Sure. And all the file descriptions are editable from the SysOp but really all you'll have to do to set it up is just to copy all your files over and then go through and do a rowse. It will tell you "Description not available" and you just hit dit to write up a short description. It's only a lot of work if you have a lot of files like you.

Chuck: I'm having typer's cramps already. However it costs to be the boss so I can't complain.

On to another subject. How about the logon data. will that still be setup the same? Selectable to go either to the printer or a disk file?

Keith: Yes it's the same as the older versions. You'll be able to use handles and such and the initial logon sequence asks quite a lot of questions so if it goes to a disk file it will take up a bit of space. You have plenty. The rest is similar to the other versions.

Chuck: Does that include download ratio's?

Keith: Yes. It saves all that data to the logfile.

Chuck: What are you going to charge for this?

Keith: I'm n ot really sure yet. It won't be much though.

Chuck: Ok what's the maximum number of active users we can have?

Keith: Well over 65 000 but Realistically you have a logical limit. See SpartaDOS can handle a single file 8 Megabytes in length. Take that number of bytes and divide it by 256 bytes [the number of bytes each userlog takes up] and you come out with around 30 000 or so.

Chuck: Well I don't think that anyone will have that many user. Even Atari Base would find it tough.

Keith: Right and that would be almost a whole Hard Drive partition just for the userlog.

Chuck: Time to buy a mainframe!

Keith: Yeah no kidding.

Chuck: What about Passwords?

Keith: On this new version the passwords are user supplied.

Chuck: Great. How many characters?

Keith: From 1 to 15 characters I believe. Again though just like the ST version...the user will be assigned a record number and if they logon with that number then the look-up time will be almost immediate.

Now they can optionally key in their Handle along with their password and then the board will search for it much like it does when you send E-Mail to somebody. It looks to see that they exist. So there are multiple ways to logon.

Chuck: Ok would you please explain again if you will the equate functions that you're supplying with the disk?

Keith: Sure. Really there's 2 sets of equates. One is the MAC/65 source code equates to all of the "Global Variables" including the SYSDATA data the USER record data Current date current time and whatever. Then there are also a set of vectors that are jump vectors. These

help you control data within the program itself.

[ZNOTE: An indepth description was given concerning these equates but this will come on the disk so we won't waste the space here going into detail.]

Chuck: Then any Atari assembler will be functional for these mods.

Keith: Correct. Yes. It's all very simple because most of the data you need is already in the shell of the program. You don't have to come up with a lot of the user input. It's already there.

Even when you're talking about really indepth utilities or games like adventures and such those things are readily accessible.

Chuck: Then are we limited to the size of these external commands?

Keith: Yes. Somewhere around 16K is the limit. That's even bigger than SpartaDOS itself so those are really involved. The shell really takes all the kluge work out of writing an assembler program. It's totally possible to write a game like Zork(tm) for on-line use if that's what you wanted to do.

Chuck: Where can the folks purchase the p rogram?

Keith: This will be through Orion Micro Systems as always. The main support/sales board will remain there.

Chuck: Can the Hard Disk User Group members get a special price on it?

Keith: I'm sure we can work something out for your members. T hose are probably the people most likely to purchase it. Sure.

Chuck: Ok I'll send Chris King at Orion a list of my members.

Keith: That'll do it.

Chuck: Next question. How many security levels are allowed on the new system?

Keith: About 320. See there are 32 Msg Bases 32 File areas [SIGS] and 32 command levels. So basically each user record has 32 flags for each of those things. Then there are other things that you would need to read the documentation to see.

Chuck: Is there an option on the new board to allow survey's?

Keith: Yes. Up to 32 trackable surveys with an un limited number of questions.

Chuck: Unlimited?

Keith: Well by disk space only.

Chuck: Superior!

Keith: Again we're talking about a BBS designed for a really big system. So by now you can probably see that this is really for a Hard Disk configuration.

Chuck: I was seriously hoping for these kinds of modifications and trvthfully there are a lot of folks going to hard disk systems. Therefore this is quite a marketable product in that sense.

Keith: Right. You can still run it from floppy but you'll be severely limited in the options allowed. Even with the use of a ramdisk.

Chuck: I see. Those folks running Megabytes and larger RAMdisks will be able to apply most of the available options.

Keith: Correct.

Chuck: Ok here's one. I know this is an important issue. Are the folks that have purchased the other express! programs going to be able to trade in their old versions for the new one?

Keith: Yes they can. Trading in the master disk for a replacement. Even tho ugh this version is being called BBS Express! Professional [Express! PRO] it is a version 2.0 upgrade of the 850 version. So those that are currently owners will be able to upgrade it for a fee that has not been set yet.

There is also going to be a 1030 version of BBS Express! Professional so that news should make everyone happy. This will be released sometime after the 850 version.

Originally we were not going to write a 1030 version. We figured hey...if you want to keep up with us you should upgrade to an 850 but we figured hey...it was really the 1030's that got us started so we'll support them too.

Chuck: I'm not sure how many folks run 1030's and Hard Drives but it's there if needed.

Keith: Right. It has now gotten to the point now where we're going to have to talk to the folks a little more now to determine what kind of system they want. We have to be sure they get the version that they can use best. With so many version out it may confuse a few.

Chuck: To be sure they don't get a Hard Disk version to run off a single drive...etc.

Keith: Right.

Chuck: Hey! Do you know what just happened?

Keith: What's that.

Chuck: I just ran out of questions!

Keith: Ha!!

Chuck: Well I sure do appreciate all this good information and I'm sure my readers do too.

So now's your chance to ramble and tell the folks what I've neglected to ask.

Keith: Well the most important thing to get across is that this is really a large system BBS program and it really does act that way.

There's 5 different logon sequences that the SysOp can use. There are a LOT of one-key commands available for the SysOp. See this version is different in that it was written more for the SysOps editability and still allows more things for the users. It's simply a better all-around program.

The nice part about it is the fact that it's what the SysOp wants.

A lot of the program isn't even written yet and I'm not really sure which way i want to go on some of the things. Sorta flying by the seat of my pants. That's why I needed some suggestions from your users. I've basically added all the features that everyone has asked for.

Chuck: Well...ending an interview especially this one is a hard thing to do but I suppose we have to do it.

Keith: Ok well let's do this... give me a call in a few minutes. I'll boot up the new version and let you take a look at what I've got completed. This way you can get a general idea of the new system.

Chuck: I'm shakin' all over! Ok and I want to thank you VERY much for this exclusive interview today!

Keith: My pleasure. No problem.

Chuck: Fantastic. Take care Keith.

Keith: See you later.

[ZNOTE: I called Keith and saw the new version a t work. I want one! I figure with all the changes that he has made it will be worth whatever he asks for it. And the option to trade in your old master for the new version is a great deal!

Plan to call Network: Atari HD Express! BBS in the next few weeks to see this version at work!

I will guarantee you wil l be impressed with his efforts and continue to support him in his endeavors.

And last but certainly not least Keith... You've done it again!

somewhere out there is a file i sent to info-atari8. it concerns an interview of Keith Ledbetter by Chuck Leazott of ZBBS in San Antonio TX about Keiths new EXPRESS BBS Professional. The transcript is due to be released in the Hard drive Users Group (run by Chuck Leazott) newsletter. Since most people probably dont belong to that users group, I have put it on this network as a public service. Replies and questions can be directed to me, and I will forward them on to Chuck. Chuck runs a BBS, but I do not have his number handy on this terminal...If you are interested, send me a mail-gram and I will copy out the info to you. I can remember that his bbs is ZBBS in the above mentioned location. it has a 1 Meg MIO and 1 or 2 Hard disk...I think 120 Meg total...and its a 130xe...thats all I remember.. oh yah...300/1200/2400. Could someone tell me where a good source of atari 8-bit archives is.
I have access to the Arpa-Internet, and the Bitnet. Although I do not
have access to things like ftp...

Interview with Kieth Ledbetter about the new Express! BBS Professional

Network: Atari and the Hard Disk User Group have recently had the
distinct pleasure of interviewing Keith Ledbetter Author of the highly
successful Express! series of Terminal and BBS Programs. This interview
centers on the newest of his BBS programs:

BBS Express! Professional

Chuck: Welcome Keith and we are honored to have this opportunity
to talk with you about you current efforts.

Keith: Thank you Chuck. It's nice to have support like yours.
```

Chuck: Believe me Keith there are hundreds more that support your work. I'm not alone. Well I have a pretty exhaustive list of questions about your newest version of BBS Express! and I'm sure the readers will be glad to hear about it.

Let me start out by asking one of the most frequently asked questions I get here. Will you allow other SysOps and programmers the opportunity to write their own files as utilities games and other things for this version?

Keith: Absolutely. This new version is dramatically different than all the others. I'll supply a list of equates for those wishing to write nice utilities for the BBS. There will also be some example programs. some source code will be on the disk

All the system vectors and variable names that point to commonly used routines will be supplied so that the bulk of utilities folks write that utilize SpartaDOS [3.2d] functions will be easier to write. You don't ha ve to write all that stuff now just use the routines already provided while writing your program around them.

Things like input/output from/to the modem etc. will be user accessible for people who want to write their own external commands.

Chuck: Which language did you use to write the new version?

Keith: Well I used my own ST and a cross assembler and ported over to the 8-Bit Atari system.

Chuck: Then which language do the programmers use to add these other options?

Keith: MAC/65 or any other machine language as long as the addressing corresponds to the correct vectors I'll supply. Probably MAC/65 will be the best for this. Anybody having experience in ML can write files for the BBS. It's real simple. Real easy for folks to write their own commands.

Chuck: What are some of the new things we can expect...Changes in format etc.?

Keith: Well you are really going to need a ramdisk or a hard disk to run this version. Most of the commands are external commands [separate files] and using a floppy will be slow to say the least. It can be done but will be very slow. You might be able to get by with a US Doubled 1050 but you're still talking about accessing the drive for every command.

You get to basically use the commands supplied and if you don't like those you can write your own. It's a real simple task.

Chuck: Whew! Let's jump ahead for a second and let me ask when this gem will be up for sale.

Keith: Oh that's really hard to say. Right now I'd say...

Chuck: ...Before this newsletter hits the stands in October???

Keith: No. right now I'd say it's about 80% complete. I'm hoping to get into Beta test by the end of this month [August] and it might be possible by October but it's really hard to say. I'll let Network: Atari and the Mouse BBS do the Beta testing.

Chuck: Music to my ears....

Keith: I figured it would be.

Chuck: OK back to configuration. I had one of my users ask if you were going to support Kermit Protocol.

Keith: No we'll support XMODEM CRC and YMODEM but not Kermit.

Chuck: You mentioned SpartaDOS 3.2d and I was wondering which other DOS's can be used.

Keith: The new system absolutely requires SpartaDOS 3.2d. No other DOS. You can use the R-TIME8 or run off of the internal software clock in SpartadOS.

Chuck: What about the Sparta-X Cartridge?

Kei th: It's being worked on right now. It should work with that because we are going to try to preserve all of the system vectors all the time/date vectors and all of that.

Chuck: Are there any forseeable problems running off of an MIO or P: R: Connection?

Keith: No I'm running it off of an MIO right now. Should be no problems at all.

Chuck: Ok how many columns support are we to expect? 38? 40? 80?

Keith: There are basically 4 sets of menus under HELP40 and HELP80 Pathnames. Support for the ST for sure and maybe VT-52. I'm still thinking about the VT-52 though. We'll see about that one. It's possible but I'm not sure at the moment.

Chuck: What about the high baud rate? What's the limit this time?

Keith: 300 through 9600 Baud.

Chuck: Will it actually do 9600?

Keith: Yes but you have to have the exact same type of modem on each end to have it work. There's not much call for it but it's there.

Chuck: I figure there's only 2 other folks out there in modem land pushing 9600 at any rate so I'm sure we don't really need it. I'm not going to go out to buy 9600 unless it becomes standard.

Keith: Right but it's in there for those that want it.

Chuck: Basically 2400 baud max will be used. Great.

Keith: Right.

Chuck: Ok What else?

Keith: Well before I let the SysOp define his/her own pathnames and such but this version has them all Hard-Coded.

You have to CREDIR each of those since they are hard-coded. All of the Sub-Directories have been set up the same. Hard-Coded. There are COMMANDS> HELP40> HELP80> BASES> USERLOG> FILES> and other subs that need creation. Also the Message Bases 32 of them are Hard-Coded. BASE01 BASE02 etc.

4000 Bytes maximum P/Message and 250 Messages P/Base. Plenty to go around I guess. That's roughly 50 lines @ 80 Columns P/Line. A short novel.

Chuck: That should make everyone happy. Is there a good Message Base Editor?

Keith: Absolutely but it's set up a bit different. Previously we had all those commands before you entered the Base but now the sub-commands come after that. I found it was easier that way.

Chuck: How about the Menu's? Will they be set-up the same? Can I use my old menu's from the old system?

Keith: No because they are set-up a little different however I may write a quick converter program to change all those over. Maybe even one for the userlog.

Chuck: Are the "letter-commands" still going to be the same?

Keith: Sure but there may be "word" command support too. The way it is now and the way it'll probably enter Beta test will be with the letter options.

Chuck: Ok. What did I forget?

Keith: You have to ask me about download files!!!

Chuck: Hehe..ok hey Keith what have you done about the 8 Pathname limit in the download section?

Keith: Well I'm glad you asked me about that. There are now 516 128 available filenames that you can have in your Massive download section!

It's set up like this: I have Hard-Coded the program to read sub-director ies FILES_01> through FILES_32>. Under each of those sub-directories are all the sub-directories that you want scanned. Figure 127 SysOp-Chosen Sub-directories under each of these FILES_xx> sub-directories and each containing 127 downloadable files you come up with the big picture.

Another way to put it is you can have sub-directories FILES_01> through FILES_32> each containing 127 sub-directories apiece and each

of those containing 127 files.

Chuck: Alright! You shouldn't have any more complaints about that!

Keith: Nope. I took care of that one for a while.

Chuck: That was probably your biggest complaint true?

Keith: Yeah that was the big one. The people that have switched to the other BBS switched because of that problem. Well now we've made the whole BBS better so I expect most of those to come back.

Chuck: I hate to admit it Keith but I was one of those that switched. I'm so ashamed. But now that we have a new toy I'll gladly switch over again to see the changes you've made. I really have to say that personally I don't care which BBS I operate but it has to suit the system I run. With 120 Meg to play with I need flexibility.

Keith: Gotta do what you gotta do.

Chuck: Sigh.

Keith: Getting back to the Downloads. Each file on the system will have a 240 character description space allotted to it just like the ST Express! BBS.

Chuck: That also takes up disk space. I can see why you need a large system.

Keith: Yes I figure everyone will go with double density and that'S why I went with 240. Each will only take up 2 sectors on the disk P/Description. But that is at the SysOps approval. If you don't want to use the descriptions you can set that up in the SYSDATA.DAT file.

Chuck: Does it have a catalog command? Like the ST version?

Keith: Better than the ST version. It will allow a catalog of the files you specify with wildcards. There will be 15 names P/Page and each one downloadable with the press of a single key.

Chuck: That sounds like it's going to take some dedicated effort by a SysOp to set it up. But once it is done you can have a class act.

Keith: Sure. And all the file descriptions are editable from the SysOp but really all you'll have to do to set it up is just to copy all your files over and then go through and do a rowse. It will tell you "Description not available" and you just hit dit to write up a short description. It's only a lot of work if you have a lot of files like you.

Chuck: I'm having typer's cramps already. However it costs to be the boss so I can't complain.

On to another subject. How about the logon data. will that still be setup the same? Selectable to go either to the printer or a disk file?

Keith: Yes it's the same as the older versions. You'll be able to use handles and such and the initial logon sequence asks quite a lot of questions so if it goes to a disk file it will take up a bit of space. You have plenty. The rest is similar to the other versions.

Chuck: Does that include download ratio's?

Keith: Yes. It saves all that data to the logfile.

Chuck: What are you going to charge for this?

Keith: I'm n ot really sure yet. It won't be much though.

Chuck: Ok what's the maximum number of active users we can have?

Keith: Well over 65 000 but Realistically you have a logical limit. See SpartaDOS can handle a single file 8 Megabytes in length. Take that number of bytes and divide it by 256 bytes [the number of bytes each userlog takes up] and you come out with around 30 000 or so.

Chuck: Well I don't think that anyone will have that many user. Even Atari Base would find it tough.

Keith: Right and that would be almost a whole Hard Drive partition just for the userlog.

Chuck: Time to buy a mainframe!

Keith: Yeah no kidding.

Chuck: What about Passwords?

Keith: On this new version the passwords are user supplied.

Chuck: Great. How many characters?

Keith: From 1 to 15 characters I believe. Again though just like the ST version...the user will be assigned a record number and if they logon with that number then the look-up time will be almost immediate.

Now they can optionally key in their Handle along with their password and then the board will search for it much like it does when you send E-Mail to somebody. It looks to see that they exist. So there are multiple ways to logon.

Chuck: Ok would you please explain again if you will the equate functions that you're supplying with the disk?

Keith: Sure. Really there's 2 sets of equates. One is the MAC/65 source code equates to all of the "Global Variables" including the SYSDATA data the USER record data Current date current time and whatever. Then there are also a set of vectors that are jump vectors. These

help you control data within the program itself.

[ZNOTE: An indepth description was given concerning these equates but this will come on the disk so we won't waste the space here going into detail.]

Chuck: Then any Atari assembler will be functional for these mods.

Keith: Correct. Yes. It's all very simple because most of the data you need is already in the shell of the program. You don't have to come up with a lot of the user input. It's already there.

Even when you're talking about really indepth utilities or games like adventures and such those things are readily accessible.

Chuck: Then are we limited to the size of these external commands?

Keith: Yes. Somewhere around 16K is the limit. That's even bigger than SpartaDOS itself so those are really involved. The shell really takes all the kluge work out of writing an assembler program. It's totally possible to write a game like Zork(tm) for on-line use if that's what you wanted to do.

Chuck: Where can the folks purchase the p rogram?

Keith: This will be through Orion Micro Systems as always. The main support/sales board will remain there.

Chuck: Can the Hard Disk User Group members get a special price on it?

Keith: I'm sure we can work something out for your members. T hose are probably the people most likely to purchase it. Sure.

Chuck: Ok I'll send Chris King at Orion a list of my members.

Keith: That'll do it.

Chuck: Next question. How many security levels are allowed on the new system?

Keith: About 320. See there are 32 Msg Bases 32 File areas [SIGS] and 32 command levels. So basically each user record has 32 flags for each of those things. Then there are other things that you would need to read the documentation to see.

Chuck: Is there an option on the new board to allow survey's?

Keith: Yes. Up to 32 trackable surveys with an un limited number of questions.

Chuck: Unlimited?

Keith: Well by disk space only.

Chuck: Superior!

Keith: Again we're talking about a BBS designed for a really big system. So by now you can probably see that this is really for a Hard Disk configuration.

Chuck: I was seriously hoping for these kinds of modifications and trvthfully there are a lot of folks going to hard disk systems. Therefore this is quite a marketable product in that sense.

Keith: Right. You can still run it from floppy but you'll be severely limited in the options allowed. Even with the use of a ramdisk.

Chuck: I see. Those folks running Megabytes and larger RAMdisks will be able to apply most of the available options.

Keith: Correct.

Chuck: Ok here's one. I know this is an important issue. Are the folks that have purchased the other express! programs going to be able to trade in their old versions for the new one?

Keith: Yes they can. Trading in the master disk for a replacement. Even tho ugh this version is being called BBS Express! Professional [Express! PRO] it is a version 2.0 upgrade of the 850 version. So those that are currently owners will be able to upgrade it for a fee that has not been set yet.

There is also going to be a 1030 version of BBS Express! Professional so that news should make everyone happy. This will be released sometime after the 850 version.

Originally we were not going to write a 1030 version. We figured hey...if you want to keep up with us you should upgrade to an 850 but we figured hey...it was really the 1030's that got us started so we'll support them too.

Chuck: I'm not sure how many folks run 1030's and Hard Drives but it's there if needed.

Keith: Right. It has now gotten to the point now where we're going to have to talk to the folks a little more now to determine what kind of system they want. We have to be sure they get the version that they can use best. With so many version out it may confuse a few.

Chuck: To be sure they don't get a Hard Disk version to run off a single drive...etc.

Keith: Right.

Chuck: Hey! Do you know what just happened?

Keith: What's that.

Chuck: I just ran out of questions!

Keith: Ha!!

Chuck: Well I sure do appreciate all this good information and I'm sure my readers do too.

So now's your chance to ramble and tell the folks what I've neglected to ask.

Keith: Well the most important thing to get across is that this is really a large system BBS program and it really does act that way.

There's 5 different logon sequences that the SysOp can use. There are a LOT of one-key commands available for the SysOp. See this version is different in that it was written more for the SysOps editability and still allows more things for the users. It's simply a better all-around program.

The nice part about it is the fact that it's what the SysOp wants.

A lot of the program isn't even written yet and I'm not really sure which way i want to go on some of the things. Sorta flying by the seat of my pants. That's why I needed some suggestions from your users. I've basically added all the features that everyone has asked for.

Chuck: Well...ending an interview especially this one is a hard thing to do but I suppose we have to do it.

Keith: Ok well let's do this... give me a call in a few minutes. I'll boot up the new version and let you take a look at what I've got completed. This way you can get a general idea of the new system.

Chuck: I'm shakin' all over! Ok and I want to thank you VERY much for this exclusive interview today!

Keith: My pleasure. No problem.

Chuck: Fantastic. Take care Keith.

Keith: See you later.

[ZNOTE: I called Keith and saw the new version a t work. I want one! I figure with all the changes that he has made it will be worth whatever he asks for it. And the option to trade in your old master for the new version is a great deal!

Plan to call Network: Atari HD Express! BBS in the next few weeks to see this version at work!

I will guarantee you wil l be impressed with his efforts and continue to support him in his endeavors.

And last but certainly not least Keith... You've done it again!

somewhere out there is a file i sent to info-atari8. it concerns an interview of Keith Ledbetter by Chuck Leazott of ZBBS in San Antonio TX about Keiths new EXPRESS BBS Professional. The transcript is due to be released in the Hard drive Users Group (run by Chuck Leazott) newsletter. Since most people probably dont belong to that users group, I have put it on this network as a public service. Replies and questions can be directed to me, and I will forward them on to Chuck. Chuck runs a BBS, but I do not have his number handy on this terminal...If you are interested, send me a mail-gram and I will copy out the info to you. I can remember that his bbs is ZBBS in the above mentioned location. it has a 1 Meg MIO and 1 or 2 Hard disk...I think 120 Meg total...and its a 130xe...thats all I remember.. oh yah...300/1200/2400. I found this article in the atari.st group. It should have been cross
posted here for all Atari owners to read.
Kit Kimes
AT&T-ISL
Naperville, IL

==========

Taken from page D-1, San Jose Mercury News, Aug 24th 1987:

"Atari to Purchase chain of retail stores." Atari will pay $67.3 million
to aquire all outstanding shares of stock at $6.25 per share. Federated
closed Friday in over-the-counter trading at $5.75.

At all Federated stores I have been to, both Commodore and Atari products
are carried.

It appears to be true. It was reported in the NY Times business section
today that Atari had announced the sale.

I don't think Keith has done this, primarily because the custom display lists
already use most of available memory. You can check on the above board.

There are version of Express for Hayes semi-compatible modems (V3), MPP
modems, and 1030 modems (V3 in beta test).

ACTION! vs. 850 handler
Re: OmniCom question
Atari 8-bit archives...
Re: (none)

------------------------------------------------------------------------

Date: 23 Aug 87 21:23:19 GMT
From: jumbo!ehs@decwrl.dec.com (Ed Satterthwaite)
Subject: ACTION! vs. 850 handler
To: info-atari8@score.stanford.edu

I am trying to turn a compiled ACTION! program into an AUTORUN.SYS file.
It needs the R: handlers that are downloaded from the 850. When I use the
standard AUTORUN.SYS file to load these handlers, then compile and run the
program, everything is ok.

When I save the compiled program, using the ACTION! monitor's WRITE
command, and append the binary to the standard AUTORUN.SYS, I get a file
that doesn't seem to work. Immediately after loading it from DOS, I get a
garbage screen and the keyboard locks up.

Since I have been able to save and run other ACTION! binaries that don't
need these handlers, I tried dumping the downloader, disassembling it to
verify that it looked relatively innocuous, and embedding it into my
ACTION! program as a ML insert. This seems to work fine when I compile
```

and run from memory, without needing the old AUTORUN.SYS file, but the saved binary does not seem to work any better.

I vaguely recall some discussion in this newsgroup of some sort of bad interaction between ACTION! binaries and the 850 handlers. Can anyone explain the problem and/or suggest a workaround.

Much thanks for any help.

The less than useful graphics characters may be corrected in later releases of OMNIVIEW. I still have the old ROM in my system but I understand that the new one supports tilde and curly braces.

Re: Hayes modem support. I have found it extremely convenient to use the OmniCom keypad editing features to program the numeral keys to send ATDT plus my favorite phone numbers. With CTRL-numeral and SHIFT/CTRL numeral, that is TWENTY possible pre-programmed autodial keys, or ten autodial keys and ten special function keys. A strip of white correction tape can be pasted across the top of the keyboard, just above the numeral keys, to remind you what the CTRL- and SHIFT/CTRL- versions of the keys do. In addition, the sequence gets displayed by Hayes modem local echo in command mode so you can see what number you are dialing.

Fred Sullivan's comments on shortcomings of OmniCom should be forwarded to David Young of CDY, as David has been extremely helpful in correcting bugs and adding useful new features when they are pointed out to him. I am sure David will want to provide excellent support to 2400-baud users and will welcome comments on the problems experienced by the few who are lucky enough to already have 2400-baud modems.

Keywords:Help!!

Line eater, eat this.....................................
I am back again looking for help in locating the official Diagnostics Diskette for 1050 disk drives. Mine has been broken for about a month now and after a dispute with the local repair shop I have decided to do my own repair. After looking around town I have found that this item is hard to get a hold of, but the service manual makes reference to it and is impossible to use without the disc to perform tests. Any help in this regard would be appreciated very much. Please e-mail any replies or info you can offer.

Thanks in advance,
mikey@molihp

514. Atari and Federated

Newsgroup: comp.sys.atari.8bit
Date: 1987-08-29 16:39:57 UTC
From: uace0@uhnix2.UUCP
Message-ID: <419@uhnix2.UUCP>
Source record: 117568
Cross-posted to: comp.sys.atari.st,comp.sys.atari.8bit

Well, this is indeed interesting what has transpired over the past week. As I understand it, Atari bought out the outstanding shares of Federated stock, which gives them approximately 30% controlling interest. Now to speculate, is this good or is this bad?

Will Atari be like ComputerLand and have a very successful marketing chain??? Or will Atari have thrown good money after bad? Let us examine a few facts:

1) Before Uncle Jack bought Atari, the corporation was on the verge of bankruptcy. They couldn't afford to buy a stick of gum let alone a portion of a chain of stores.

2) Atari in Europe? Before: NO; Now: it is a very serious business machine. From the quality of software which I have seen coming from the European market, it is obvious that at least some of the Europeans take the STs to be more of a machine than here in the states.

3) Before: Waste, waste, waste. Now: Lean, mean, fighting machine. The company is efficient in what it does (even if Uncle Jack is very tight with the money he spends - example: no CD ROMs because he can't get his price). This means the Atari passes on the savings to it's customers (although sometimes the quality may be on the edge, but generally it all works. I have a REV A board and have never had troubles with it.. now my REV C...)

4) Jack is shrewd. Personally, my great-grandfather was a victim of WWII, he was in Auswitz (forgive spelling if incorrect), and I know that he was a survivor because of this. Jack, too, is a survivor, and I believe that he is not about to do something which will jeapordize his future (he got this far didn't he).

So now we have this deal with Federated. Is it good or is it bad. No one except Uncle Jack and his family and advisors know what is going to be done. We can only speculate that from his past record (made Commodore, rebuilt Atari) that he is a winner, and he does things that will be successful. So, we know at least one thing is for certain: Uncle Jack sees this move as a way to make more money for him and his siblings. One point for the Tramiels.

Now for the consumer, and the retail merchant. This is a toss up. The consumer thus far has gotten a good machine for a very reasonable price. The MEGAs are here and a bit more expensive (but they are nicer machines, and a bit more complete). So, the consumer must pay more for more machine. This is reasonable. Still, the consumer still is getting a good deal for his money. And if we use the age old standard of measuring bytes per dollar, the new MEGAs are coming in at a much cheaper price per K than any other machine. So in this light the consumer still gets more (even though (s)he pays more).

The retail merchant. Bye-Bye. Jack has seen cut-throat prices on the STs. Mail order this, mail order that. Is the Apple Mac sold mail order? Do I as a professional want to buy a mail order computer. I think not. So now Uncle Jack says, "You must have an on site technician and an outside sales rep to sell the MEGAs." Ahhhh, Uncle Jack is trying to save his profit margin (shrewd). So he goes out and purchases a retail outlet (even if Fred Rated is their spokesman). Can Jack now change the image of the Atari machines buy specifying how they are sold and creating a specific environment for them to be sold in. I can only suggest that other retail chains have changed their images successfully (take J.C. Penney, for example), so maybe Jack can too. As for the independent computer store that we as Atarians have always revelled in: I can only say, "May the SCHWARTZ be with you." If Atari wants to save its butt, someone will have to be the fall-guy. Personally, I would hate to see the store in town here (Computers-to-Grow) which has been struggling but has been open for about 4-5 years now (and faithfully Atari- they have done alot for the Atari community and user support groups) close shop. This would be a detriment to people out there who desperately need help iwth the computer, and need help from people who like the machines and company (usually) and provide excellent user support. I have seen the guys a CTG spend (on more than one occasion) 2-4 hours with a customer explaining the machine, providing answers to questions. Not to mention that they provided about 500 t-shirts for the computer fair we had on campus last year, plus about half-a-dozen machines for it too. I would hate to see an excellent source of help go out the window.

(Sorry for that... I'm off my soapbox, now)

I am in no way affiliate with any computer store or CTG. I just know that a retail chain can't provide support (which Atari **NEEDS** to have) like the independent.

---------- The Bottom Line ----------
Atari is going to make money with this deal (although at least 4 Federated stores have closed down here in Houston in the past year- they expanded too quickly in my opinion: greed), but at who's expense. Not mine, that's for certain. I am fortunate in that I know what I am doing with computers, I have the knowledge to make any system what I need it to be. If the MEGA is what I need, then I will get it, and probably at a good price too. I'm just glad I didn't finance Atari with my investments by opening up a business to sell only Atari computers.

The winner: ATARI for sure.
Runner up: The consumer (good prices are certain, but user support (???))
Last place: the independent computer store in town.

Find a way to get rid of mail order, but not the local stores, different than what Jack is doing and you will have a successful computer company too.

(Sorry this was so long)

================================================================================
Taken from page D-1, San Jose Mercury News, Aug 24th 1987:
```

"Atari to Purchase chain of retail stores." Atari will pay $67.3 million
to aquire all outstanding shares of stock at $6.25 per share. Federated
closed Friday in over-the-counter trading at $5.75.

At all Federated stores I have been to, both Commodore and Atari products
are carried.

I don't think Keith has done this, primarily because the custom display lists
already use most of available memory. You can check on the above board.

There are version of Express for Hayes semi-compatible modems (V3), MPP
modems, and 1030 modems (V3 in beta test).

I believe CDY most frequently advertises in ANALOG Magazine these days. With the gradual shift in interest toward 16-bit machines, they may not advertise as much currently as in former years. Anyway, their address is

CDY Consulting, Inc.
421 Hanbee
Richardson, TX 75080.

Phone is (214) 235-2146. David Young, the proprietor of CDY, is usually available in the evening to take orders and/or answer technical questions about his company's products.

-John Sangster / jhs@mitre-bedford.arpa

(I have no finanicial interest in or connection with CDY other than as a customer.)

520. simple downloader...

Newsgroup: comp.sys.atari.8bit
Date: 1987-08-31 20:06:22 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8708312006.AA24338@mitre-bedford.ARPA>
Source record: 117574

```
The following is approximately what the Avatex modem user manual provides
for a dumb ASCII terminal program to get on the air with. It may or may not
work "right out of the box" for you but you should be able to get it working
with a little experimentation.
------------------------------c-u-t---h-e-r-e---------------------------------
10 GOTO 300:REM Dumb Terminal Prog.
100 STATUS #3,AVAR:IF PEEK(747)=0 THEN 200
120 GET #3,CHAR:IF CHAR=0 OR CHAR=10 THEN 200
130 PUT #4,CHAR
200 IF PEEK(764)=255 THEN 100
210 GET #2,KEY:PUT #3,KEY:GOTO 100
300 REM I/O Setup for Dumb Terminal.
310 OPEN #2,4,0,"K:"
320 OPEN #3,13,0,"R:"
330 OPEN #4,8,0,"E:"
340 XIO 34,#3,192+48+3,0,"R:"
350 XIO 40,#3,0,0,"R:"
360 GOTO 100:REM Go to it!
------------------------------c-u-t---h-e-r-e---------------------------------
The above just does a loop that checks for an incoming character (line 100)
and if it gets one, slaps it on the screen (line 130), then checks the
keyboard for input (line 200) and if it sees that a character was pressed
(loc. 764 not = 255), slings it out to the outgoing side of the R: device.

*****> If you are adventuresome, you can turn this simple program into a
version that can capture a file off the modem. One way to do this would
be to change line 330 to open a file "D1:YOURFILE.EXT" or whatever. Be
sure to close the file first; in fact, my standard practice is NEVER to
OPEN a file without CLOSING it first -- saves a whole lot of dumb error
messages. The program below has this feature added. Possibly the simplest
way to capture a file is to press BREAK, change line 350 to have a
device:filename specification inside the quotes, and type "RUN" again.
Then type the command to send the file. When it has finished being sent,
press BREAK, type CLOSE #4, and that should do it.
------------------------------c-u-t---h-e-r-e---------------------------------
10 GOTO 300:REM Dumb Terminal Prog.
100 STATUS #3,AVAR:IF PEEK(747)=0 THEN 200
120 GET #3,CHAR:IF CHAR=0 OR CHAR=10 THEN 200
130 PUT #4,CHAR
200 IF PEEK(764)=255 THEN 100
210 GET #2,KEY:IF KEY=
220 PUT #3,KEY:GOTO 100
300 REM I/O Setup for Dumb Terminal.
310 CLOSE #2:OPEN #2,4,0,"K:"
```

```
320 CLOSE #3:OPEN #3,13,0,"R:"
330 CLOSE #4:OPEN #4,8,0,"E:" <---- change E: to your Dn:FILE.EXT
340 XIO 34,#3,192+48+3,0,"R:"
350 XIO 40,#3,0,0,"R:"
360 GOTO 100:REM Go to it!
```

------------------------------c-u-t---h-e-r-e--------------------------------

This may or may not work without fiddling, but it ought to be reasonably easy to get it working. And it surely is the simplest way to get a downloading capability -- as well as learning a lot in the process! If you get it working, let me know and I will send you uudecode and a fancier terminal emulator or two.

-John S., jhs@mitre-bedford.

One source of parts and schematics is American Techna-Vision. They have the SAMS service manual for the 1050 for $19.50. They have IC's, circuit pack assemblies and complete drive mechanisms. Their address is:

American Techna-Vision
15338 Inverness St.
San Leandro, CA 94579
1-800-551-9995 or
(415)-352-3787

They accept credit cards. They also do repair if you can't figure out the problem. Service rate for the 1050 is $85.

Hope this helps...

523. Re: Atari and Federated

Newsgroup: comp.sys.atari.8bit
Date: 1987-09-02 00:46:19 UTC
From: cas@dasys1.UUCP
Message-ID: <1167@dasys1.UUCP>
Source record: 117577
Cross-posted to: comp.sys.atari.st,comp.sys.atari.8bit

As a computer consumer, and the proud owner of an Atari ST, I would like to withhold my opinion as to whether or not Atari buying the Federated chain was a good move. I would like to say that being in New York, finding well stocked Atari stores are few and far between. There are a few stores here and there that stock Atari computer hardware and several of the more popular titles. Unfortunately there are only one or two stores in my area that stock a relatively full line (I only know of two such stores and they are at least an hour away by car). More and more of my purchases are having to be done by mail order. The point behind my message is that Atari is obviously going to stock the Federated store chains preferrentially with their products. What will happen to the supply of Atari computer equipment (both hardware and software) in other areas of the country?

524. BASIC XE

Newsgroup: comp.sys.atari.8bit
Date: 1987-09-02 15:20:45 UTC
From: SAULNIER@cg-atla.UUCP
Message-ID: <770@cg-atla.UUCP>
Source record: 117578

I purchased "BASIC XE" from OSS some time ago, and I realized
that I NEVER use atari BASIC anymore. My question is, can I yank out
the ATARI BASIC rom(s) and do a straight swap with the "XE" roms? I
would like to free up the bus connector for other uses, but can't
because this cartridge is ALWAYS installed. Has anyone ever done
this?? (I could handle more than a straight swap if someone has
the exact procedure.)

Thanx in advance.

525. October 1987 ANTIC TOC

Newsgroup: comp.sys.atari.8bit
Date: 1987-09-03 18:42:55 UTC

OCTOBER 1987 ANTIC TOC

page article

8 I/O BOARD
Letters from Readers.
12 PRODUCT REVIEWS
Software
Guitar Wizard (Baudville)
Linkword Languages (Artworx Software)
Ultra Menu (Computer Software Services)
Hardware
Ultra-Speed (Computer Software Services)
15 SUPER DISK BONUS
The bonus program for disk subscribers this month is
the ANTIC Spelling Checker that allows up to 10 personal
dictionaries of approximately 6300 words each.
16 STARTING OUT: ATARI ANIMATION
This is the fifth lesson in the series. It covers bit
mapping and has an interesting demo.
24 GAME OF THE MONTH: RESISTORS
This action game teaches binary and electronics. It uses
a redefined character set for the graphics. BASIC
27 USERS GROUP: ACENET
A discussion of the 17 Southern CA user groups that make
up ACENET.
32 NEW PRODUCTS
A description but not a review of several new products
available for the Atari computers.
This month they describe the Okidata 180 printer, Cycle
Knight (Artworx Software), the pocket calculators with the
Atari logo on them, Microstuffer (Supra) and XR 100 Bar
Coder (Xenia Research)--an inventory bar code reader.
33 PAGE 6 EXCHANGE: GRAPHICS IMPOSSIBLE
Two eye-popping demos of graphics techniques often mistakenly
considered impossible--mixed vertical display lists and dual
players on the same horizontal line.
37 FOOTBALL PREDICTOR
A program that helps you pick the winners and beat the points
spread. It is claimed that this program had nearly a 60%
success rate against the points spread last year.
39 TELEPROMPTING WITH ATARI
An article on how Q-Tv of Los Angles use the Atari 130XE
as the basis of a teleprompting system.
40 ANTIC PROMPTER

Now you too can use your Atari to prompt you when you give
those important speeches at club meetings, etc. This
program will read a file written in AtariWriter, Paper Clip
or its own editor and display it in large letters. You use
the joystick to select speed and direction.
42 MAVERICK ATARI SCHOOL
A writeup on the PCS School for Advanced Learning in Nampa,
Idaho.
44 BONUS GAME: MATH FLASHCARDS
No fancy graphics. Just a direct, no-nonsense program that
kids enjoy using.
46 BONUS GAME: NAME THE PRESIDENTS
A simple, short program helps youngsters learn the Presidents
of the U.S.
47 CHECKBOOK BALANCER
A compact but powerful user-friendly calculating database.

**********BEGIN THE ST RESOURCE SECTION**********

52 ANTIC PROMPTER ST
Now you too can use your Atari to prompt you when you give
those important speeches at club meetings, etc. This
program is written in GFA BASIC, runs on any color or
monochrome ST and will smoothly scroll text files (using
very large letters) up the TV screen at speeds ranging from
very slow to faster than most people can talk.

The following is approximately what the Avatex modem user manual provides
for a dumb ASCII terminal program to get on the air with. It may or may not
work "right out of the box" for you but you should be able to get it working
with a little experimentation.

```
------------------------------c-u-t---h-e-r-e---------------------------------
10 GOTO 300:REM Dumb Terminal Prog.
100 STATUS #3,AVAR:IF PEEK(747)=0 THEN 200
120 GET #3,CHAR:IF CHAR=0 OR CHAR=10 THEN 200
130 PUT #4,CHAR
200 IF PEEK(764)=255 THEN 100
210 GET #2,KEY:PUT #3,KEY:GOTO 100
300 REM I/O Setup for Dumb Terminal.
310 OPEN #2,4,0,"K:"
320 OPEN #3,13,0,"R:"
330 OPEN #4,8,0,"E:"
340 XIO 34,#3,192+48+3,0,"R:"
350 XIO 40,#3,0,0,"R:"
```

```
360 GOTO 100:REM Go to it!
------------------------------c-u-t---h-e-r-e---------------------------------
```
The above just does a loop that checks for an incoming character (line 100) and if it gets one, slaps it on the screen (line 130), then checks the keyboard for input (line 200) and if it sees that a character was pressed (loc. 764 not = 255), slings it out to the outgoing side of the R: device.

*****> If you are adventuresome, you can turn this simple program into a version that can capture a file off the modem. One way to do this would be to change line 330 to open a file "D1:YOURFILE.EXT" or whatever. Be sure to close the file first; in fact, my standard practice is NEVER to OPEN a file without CLOSING it first -- saves a whole lot of dumb error messages. The program below has this feature added. Possibly the simplest way to capture a file is to press BREAK, change line 350 to have a device:filename specification inside the quotes, and type "RUN" again. Then type the command to send the file. When it has finished being sent, press BREAK, type CLOSE #4, and that should do it.

```
------------------------------c-u-t---h-e-r-e---------------------------------
10 GOTO 300:REM Dumb Terminal Prog.
100 STATUS #3,AVAR:IF PEEK(747)=0 THEN 200
120 GET #3,CHAR:IF CHAR=0 OR CHAR=10 THEN 200
130 PUT #4,CHAR
200 IF PEEK(764)=255 THEN 100
210 GET #2,KEY:IF KEY=
220 PUT #3,KEY:GOTO 100
300 REM I/O Setup for Dumb Terminal.
310 CLOSE #2:OPEN #2,4,0,"K:"
320 CLOSE #3:OPEN #3,13,0,"R:"
330 CLOSE #4:OPEN #4,8,0,"E:" <---- change E: to your Dn:FILE.EXT
340 XIO 34,#3,192+48+3,0,"R:"
350 XIO 40,#3,0,0,"R:"
360 GOTO 100:REM Go to it!
------------------------------c-u-t---h-e-r-e---------------------------------
```
This may or may not work without fiddling, but it ought to be reasonably easy to get it working. And it surely is the simplest way to get a downloading capability -- as well as learning a lot in the process! If you get it working, let me know and I will send you uudecode and a fancier terminal emulator or two.

Subject: Quasi termcap entry ?
To: info-atari8@score.stanford.edu

Since the famed 800 really has no termcap entry as per UNIX
I was wondering if anyone has come up with something that
will work -- especially in the unix editor, vi.
When I say termcap (for those of you who don't know)
I mean things like this:
cr=^M
bel=^G
...etc

All reponses will be appreciated

My 1050 disk drive died recently and I'm wondering where to get schematics.
The power on/off LED comes on, but nothing happens after that. I put a disk in
and nothing. I took it apart and nothing wrong was obvious visually. I
measured the voltage from Vdd-Gnd on various dips, but got nothing. I'm
wondering if the power supply died. Have any info?

Using what terminal program??? I use the vt100 termcap with Omnicom
doing vt100 emulation, and vt52 or adm3a termcaps using Chameleon with vt52
or adm3a emulation.

(Admittedly I made a slight modification to the vt100 termcap, putting in
a delay on reverse scroll, but that only matters with emacs at 2400 baud.)

One source of parts and schematics is American Techna-Vision. They have the
SAMS service manual for the 1050 for $19.50. They have IC's, circuit pack
assemblies and complete drive mechanisms. Their address is:

American Techna-Vision
15338 Inverness St.
San Leandro, CA 94579
1-800-551-9995 or
(415)-352-3787

They accept credit cards. They also do repair if you can't figure out the
problem. Service rate for the 1050 is $85.

Hope this helps...

OSS'S BASIC XE is a 16K BASIC that bank-switches a portion of its 8K
physical address space. In addition, it makes use of the 8K RAM
shadowed by the cartridge through disk loaded extensions. This
allows the versatility of a 24K language while only occupying 8K of
the limited 6502 address space. In extended mode, it stores its
program code in the extra 64K of RAM banked on the 130XE, using the
main memory for data storage only. Alternately you can kleep
program and main line data storage in the main bank, and do extended
storage of data chunks in the banks (explicit bank numbers can be
used with peeks, pokes, bloads etc.).

You can see that this would not be a simple ROM replacement, since
you would also have to graft the banking logic.

A simpler approach might be to use ICD's 130XE bus adapter that
converts the 130XE cartridge and extended slot to the straight 800XL
type connector, while adding two (vertical) cartridge slots. The
second slot is intended for the R-TIME8 cartridge.

What might be a better solution and certainly a simpler one is:::

There is a company out there called 'ICD' that makes nice things for the 8-bit
machines. One of them is an external 'MULTI IO' which plugs into the
external bus of the XL machines. But what about the XE's you ask.
For $19.95 they will sell you an adapter to plug into the XE's bus that
converts into the XL's bus. On this adapter are two cartridge sockets.
The sockets are identical, so you can't have two standard carts plugged
in at the same time, but something like the 'R-TIME 8' cart could be
in the other socket.

The XL bus and the XE bus differ only by pin-out. This adapter will give
you a place to plug your 'XE BASIC' and give you an XL bus pin-out.

NOW to answer your question!!
The 'XE BASIC' system is a bank switched cart. The Atari basic is not
banked. While the mod is possible, it may not be easy, because of the
bank switching required by the 'XE BASIC'.

You can order from ICD via their BBS.
1-815-968-2229

As usual, I am not connected with ICD, just a happy customer!!

Ted Burger

529. Re: Simple Downloader Idea -- "Oops!"

Newsgroup: comp.sys.atari.8bit
Date: 1987-09-04 14:58:05 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8709041458.AA29863@mitre-bedford.ARPA>
Source record: 117583

David Young and John Dunning (both authors of kermit download programs themselves) pointed out to me that my suggestion of modifying the Avatex Modem people's "dumb terminal" BASIC program to download files contained a -- how shall I put it -- an oversimplification. (There, that doesn't make me sound too stupid now, does it?!)

Unfortunately, -- since it really would be nice to have such a simple, type-in program -- in order to do disk I/O on the serial bus, you have to shut down or at least suspend RS-232 port operations. So just redirecting the output from the screen to the disk won't work. It gets pretty complicated, apparently.

If anybody is working on the problem, one suggestion both Dunning and Young made was to buffer the data internally, presumably in a very long string variable, then after transmission was complete, to copy it out to a file. There would be a fairly stringent limit on file size that could be handled, like (wild guess) maybe 10K bytes. Whatever the limit, it would be too small to handle a program as big as CDY's OmniCom or Dunning's kermit65 in one chunk. It would be possible to break it up into 4 or so chunks and send them as separate files, then reassemble them at the other end. Another possibility would be to write an intermediate version of the program that has the flow control trickery in it to handle large files but is not a really nice, full-featured terminal emulator. But it could be short enough to download in one block, using the rudimentary, type-in version. Somebody out there who really needs it, please volunteer to be the chief nagger and tester!

I apologize for my error. In my defense I can only say that anybody who got snookered into trying to make the program work will undoubtedly have learned a lot in the process!

531. 600XL Upgrade to 256k ? Where and How?

Newsgroup: comp.sys.atari.8bit
Date: 1987-09-06 01:47:31 UTC
From: hpchang@watmath.UUCP
Message-ID: <14540@watmath.waterloo.edu>
Source record: 117585

I would like to ask for your help in finding a way to upgrade the Atari
600xl to 256k. I would appreciate any help on this...
Thanks in advance.....

532. Won't boot from harddisk (WAS: Re: XT Problems)

> it might be worth a try ...

I've also seen the problem encountered by George, but my solution was somewhat different from Ed's. My system, too, started having trouble booting from the hard drive until it was warmed up. After a while, it wouldn't boot even after a several hour warm-up period. At this point, I decided to check things out.

It would seem that because of repeated hot/cold spells (hot when running, cold when powered off), the socketed IC's worked themselves loose. After removing each board in the system and re-seating those IC's that were in sockets (I just pushed them down all the way), the boot-up problem was cured.

This solution is similar to Ed's, in that the probable cause was insufficient contact between parts, with the solution being to re-establish good contact.

Just thought I'd pass this along.

By the way (flame-retardant suit on), I felt that George's problem was probably common to all micros so I have cross-posted this article, with the solutions used by Ed and me, to (what I considered to be) all the comp.sys.* groups involving micros. I appologize in advance if I have offended anyone in doing so. Please edit the Newsgroups: line if you wish to followup to this article in a system-specific way.

```

Ultra-Speed (Computer Software Services)
15 SUPER DISK BONUS
The bonus program for disk subscribers this month is
the ANTIC Spelling Checker that allows up to 10 personal
dictionaries of approximately 6300 words each.
16 STARTING OUT: ATARI ANIMATION
This is the fifth lesson in the series. It covers bit
mapping and has an interesting demo.
24 GAME OF THE MONTH: RESISTORS
This action game teaches binary and electronics. It uses
a redefined character set for the graphics. BASIC
27 USERS GROUP: ACENET
A discussion of the 17 Southern CA user groups that make
up ACENET.
32 NEW PRODUCTS
A description but not a review of several new products
available for the Atari computers.
This month they describe the Okidata 180 printer, Cycle
Knight (Artworx Software), the pocket calculators with the
Atari logo on them, Microstuffer (Supra) and XR 100 Bar
Coder (Xenia Research)--an inventory bar code reader.
33 PAGE 6 EXCHANGE: GRAPHICS IMPOSSIBLE
Two eye-popping demos of graphics techniques often mistakenly
considered impossible--mixed vertical display lists and dual
players on the same horizontal line.
37 FOOTBALL PREDICTOR
A program that helps you pick the winners and beat the points
spread. It is claimed that this program had nearly a 60%
success rate against the points spread last year.
39 TELEPROMPTING WITH ATARI
An article on how Q-Tv of Los Angles use the Atari 130XE
as the basis of a teleprompting system.
40 ANTIC PROMPTER
Now you too can use your Atari to prompt you when you give
those important speeches at club meetings, etc. This
program will read a file written in AtariWriter, Paper Clip
or its own editor and display it in large letters. You use
the joystick to select speed and direction.
42 MAVERICK ATARI SCHOOL
A writeup on the PCS School for Advanced Learning in Nampa,
Idaho.
44 BONUS GAME: MATH FLASHCARDS
No fancy graphics. Just a direct, no-nonsense program that
kids enjoy using.
46 BONUS GAME: NAME THE PRESIDENTS
A simple, short program helps youngsters learn the Presidents
of the U.S.
47 CHECKBOOK BALANCER
A compact but powerful user-friendly calculating database.

**********BEGIN THE ST RESOURCE SECTION**********

52 ANTIC PROMPTER ST
Now you too can use your Atari to prompt you when you give those important speeches at club meetings, etc. This program is written in GFA BASIC, runs on any color or monochrome ST and will smoothly scroll text files (using very large letters) up the TV screen at speeds ranging from very slow to faster than most people can talk.

63 SOFTWARE LIBRARY
This section contains all the program listings for the articles in this issue.
82 TECH TIPS
This section is a collection of tips and short programs from readers or collected from various Users Groups newsletters.

Comments: One of the products reviewed this month is Ultra-Speed, a replacement OS chip for XL/XE machines that allows high-speed access with most disk drives modifications and virtually all software. It allows you to switch between it and the original OS. It provides a true cold-start by pressing [HELP] and [RESET]. There is a new regular feature in ANTIC called Page 6 Exchange. It consists of programs originally published in a British publication called Page 6. They, in turn, will be able to print programs from ANTIC.

OSS'S BASIC XE is a 16K BASIC that bank-switches a portion of its 8K
physical address space. In addition, it makes use of the 8K RAM
shadowed by the cartridge through disk loaded extensions. This
allows the versatility of a 24K language while only occupying 8K of
the limited 6502 address space. In extended mode, it stores its
program code in the extra 64K of RAM banked on the 130XE, using the
main memory for data storage only. Alternately you can kleep
program and main line data storage in the main bank, and do extended
storage of data chunks in the banks (explicit bank numbers can be
used with peeks, pokes, bloads etc.).

You can see that this would not be a simple ROM replacement, since
you would also have to graft the banking logic.

A simpler approach might be to use ICD's 130XE bus adapter that
converts the 130XE cartridge and extended slot to the straight 800XL
type connector, while adding two (vertical) cartridge slots. The
second slot is intended for the R-TIME8 cartridge.

Subject: Re: Simple Downloader Idea -- "Oops!"
Date: Fri, 04 Sep 87 10:58:05 EDT
From: jhs@mitre-bedford.ARPA

David Young and John Dunning (both authors of kermit download programs
themselves) pointed out to me that my suggestion of modifying the Avatex
Modem people's "dumb terminal" BASIC program to download files contained
a -- how shall I put it -- an oversimplification. (There, that doesn't
make me sound too stupid now, does it?!)

Unfortunately, -- since it really would be nice to have such a simple, type-in program -- in order to do disk I/O on the serial bus, you have to shut down or at least suspend RS-232 port operations. So just redirecting the output from the screen to the disk won't work. It gets pretty complicated, apparently.

If anybody is working on the problem, one suggestion both Dunning and Young made was to buffer the data internally, presumably in a very long string variable, then after transmission was complete, to copy it out to a file. There would be a fairly stringent limit on file size that could be handled, like (wild guess) maybe 10K bytes. Whatever the limit, it would be too small to handle a program as big as CDY's OmniCom or Dunning's kermit65 in one chunk. It would be possible to break it up into 4 or so chunks and send them as separate files, then reassemble them at the other end. Another possibility would be to write an intermediate version of the program that has the flow control trickery in it to handle large files but is not a really nice, full-featured terminal emulator. But it could be short enough to download in one block, using the rudimentary, type-in version. Somebody out there who really needs it, please volunteer to be the chief nagger and tester!

I apologize for my error. In my defense I can only say that anybody who got snookered into trying to make the program work will undoubtedly have learned a lot in the process!

What might be a better solution and certainly a simpler one is:::

There is a company out there called 'ICD' that makes nice things for the 8-bit machines. One of them is an external 'MULTI IO' which plugs into the external bus of the XL machines. But what about the XE's you ask. For $19.95 they will sell you an adapter to plug into the XE's bus that converts into the XL's bus. On this adapter are two cartridge sockets. The sockets are identical, so you can't have two standard carts plugged in at the same time, but something like the 'R-TIME 8' cart could be in the other socket.

The XL bus and the XE bus differ only by pin-out. This adapter will give
you a place to plug your 'XE BASIC' and give you an XL bus pin-out.

NOW to answer your question!!
The 'XE BASIC' system is a bank switched cart. The Atari basic is not
banked. While the mod is possible, it may not be easy, because of the
bank switching required by the 'XE BASIC'.

You can order from ICD via their BBS.
1-815-968-2229

As usual, I am not connected with ICD, just a happy customer!!

I would like to know what the pinout of the 1200xl's port b is. also, which pin on the 6520 corresponds to bit 0 (I assume the rest are meerly increments of bin and bit). Also, there have been some rumors on occasion that the CPU in the Atari 8 bitters is a custom CPU with a 6502 instruction set. Is this true? If so, what changes were made? I have a 65C802 CPU (16 bit, 6502 pin compatible) that I would like to drop into my 1200 or 130XE. A friend has done this with a Vic-20 (no laughs please) and had no problems...except his games sped up. Comments and suggestions are welcome.

Message-ID: <870907174221.284781@DOCKMASTER.ARPA>
Source record: 117591

Ok, I have just found out that the 1200xl (and I presume everything else but the 400 and 800) does NOT have a standard 6502 in it. Can anyone answere the questions of the day? Namely, what was done to the processor to make it non-standard? I suspect that the boot vector (as well as some others) have been changed from the standard 6502 vectors. If you dont know for sure, but could tell me how to talk to somebody at Atari...I would appreciate that greatly. Otherwise, suggestions and comments are welcome...results will be posted (if there are any). The second question concerns the OS source code. Has the OS source been published for the xl/xe machines (i have a 1200xl and a 130xe). If it has been published, who and where??? If not...does anyone have a suggestion for writing an OS? I want to use a regular 6502 in my 1200xl and I think I will need to change the OS startup vectors (see question number 1 above). Better yet, are there any "alternate OS" available for the ataris...and would any of the authors be willing to release the source under a non-disclosure agreement or make a custom version?

please address replies to Cothrell -at DOCKMASTER.ARPA or to Info-Atari8
thanks...Scott Cothrell Cothrell -at DOCKMASTER.ARPA.

538. CC8 Compiler Version 2.3b (1 of 3)

Newsgroup: comp.sys.atari.8bit
Date: 1987-09-08 20:32:10 UTC
From: smk@cbterra.ATT.COM
Message-ID: <3700@cbterra.ATT.COM>
Source record: 117592

This is version 2.3b of CC8, an improved version of the Deep Blue C
Compiler. The version fixes a particularly nasty bug found by
John Dunning (#4 below) and has some other differences from the original
posted version (detailed below).

Part 1 -- this article
Part 2 -- the original CC8 doc
Part 3 -- the uuencoded CC8.COM (33732 bytes, 24465 bytes uudecoded)

Steve Kennedy {ihnp4,moss,decwrl,?}!cbosgd!smk

The following is a list of fixed bugs, enhancements, and known problems:

Bug fixes:

1. Empty expressions in for statement accepted, i.e.,

for(;;;) $($)

2. Constant expression are now valid after "case", i.e.,
"case 2*3." (fixes "case -1:" problem)

3. "*a" if a is an array no longer generates an error.

4. A function argument declaration of "type var[]" is now
converted to "type *var." Previously, the compiler generated
bad code which caused a lock-up when the resulting program
was run (e.g., programs using "getname()" in ACECIO.C).

Enhancements:

1. The expressions "a[x]" and "x[a]" are both valid and
equivalent provided one of x or a is a pointer or array.

2. structs without explicit tag names are now legal, i.e.,

"struct $(.... $) y;"

3. The compiler now recognizes the keywords "short" and "long."
Note that "int" = "short" = "short int" = "long" = "long int"
= 2 bytes. "Long" declarations produce the warning
"long == short."

4. The compiler now recognizes the keyword "unsigned" and
will generate unsigned comparison code for <, <=, >, or >=
when one or both operands are unsigned.

Caveats:

- You'll have to write your own routines to print these
correctly (no %u in ACE C or DBC printf).

- I'm not sure *, /, or % work properly on unsigned numbers.

Known problems (send mail or post if you want to add to the list):

1. Not all escape sequences recognized by ACE C are recognized by
CC8. (\u, \d, \l, \r, \e)

2. Compiler doesn't like "register x" although it will accept
"register int x." Note that "register" doesn't do anything
special anyway.

539. CC8 Compiler Version 2.3b (2 of 3)

Newsgroup: comp.sys.atari.8bit
Date: 1987-09-08 20:33:47 UTC
From: smk@cbterra.ATT.COM
Message-ID: <3701@cbterra.ATT.COM>
Source record: 117593

CC8 DOCUMENTATION

This compiler is an upgrade version of the Deep Blue C (DBC) compiler which supports more features of standard C and is much faster. It generates the same kind of pseudo code as DBC and ACE C and can be used with either's linker and runtime engine. I recommend using ACE C for its speed and expanded features. This document gives a brief overview of the extended features of the compiler along with its limitations.

This document is not intended as a C tutorial, nor is it intended as a tutorial for DBC or ACE C. Features such as assembly language protocol, built-in routines, and floating point depend solely upon the type of linker and runtime system you are using, and NOT upon this compiler.

PREPROCESSING

CC8 supports all preprocessor functions except for #line. This includes macro functions, #ifdef, #ifndef, #if, and #undef. In addition,

o #include files may be nested (currently only 2 deep)

o no restriction on placement of comments

o the TAB character may be used as white space.

o predefined symbols __LINE__ (replaced by current line number) and __FILE__ (replaced by current file name).

o #ifdef, #ifndef, and #if may be nested (5 deep maximum).

Caveats:

- "bizarre" usage of #define macros may not work as expected (or at all)

- in the "skipped" section of an #ifdef-#else-#endif group, comments are not processed. Thus it is not a good idea to "comment out" #else's or #endif's.

VARIABLE DECLARATIONS

CC8 supports more complex type constructions than DBC or ACE C, e.g., pointers to pointers. In addition, the types struct, union, and enum have been added and variables can be declared static.

o multidimensional arrays may be declared.

o functions may be declared as returning char, int, or pointer
to anything. Pointers to functions, arrays of pointers to
functions, etc, may be declared. Note: a pointer to a
function must now be used correctly:

(*pf)();

not

(pf)();

o variables declared as type "enum x" are really declared as
type "int"; the name "x" is ignored. Note that user
assignment of numbering scheme is implemented, e.g.,

enum colors $(red = 2, white = 0, blue $);

assigns red = 2, white = 0 and blue = 1.

o external array declarations of the form

extern int array_name[];

are now valid.

o in expressions, the sizeof and type cast operators may be
used.

Caveats:

- no float/double declarations (but a limited floating point is
available when ACE C's linker and runtime engine are used)

- all struct/unions must have a tag name

- all global symbols, struct/union tags and components are drawn
from the same name pool.

- no bit fields

- identical declarations of a variable neither cause and error
nor do they work reasonably. For example,

int a; int a;

will silently declare "a" twice and confuse the linker.

COMPILE TIME EVALUATION OF CONSTANT EXPRESSIONS

CC8 supports a limited form of compile time evaluation of
constant expressions. A constant expression is defined as
any expression containing integer constants, character constants,
sizeof, or a constant expression separated by one or more operators
in one of the following groups, "|", "^", "&", "==", "!=", ">> <<",
"+ -", "* / %", or prefixed by one of the unary operators, "-",
"!", "$-". Evaluation follows normal rules of operator precedence
and can be overridden by parentheses. Examples:

```
x = 12*24 + 13; => x = 301;

x = 12 + 13 + y; => x = 25 + y;

x = y + 12 + 13; => x = y + 12 + 13; (1)

x = y + 12*13; => x = y + 156; (2)

x = y + (12 + 13) => x = y + 15; (3)

1. compiler "gives up" after finding non-constant 'y'.

2. '*' is in a different group than '+' and appears to the compiler
as a separate expression.

3. Parentheses force compiler to treat "12 + 13" as a subexpression.

Constant expressions may be used in array declarations, initializers,
and #if.

INITIALIZERS

CC8 supports initialization of global variables of type char, int,
pointer, array, struct/union, and enum. The syntax is a subset of that
allowed by standard C.

Rules:

1. Simple types (char, int, pointer) can be initialized by
a constant expression. The constant expression must not
be enclosed inside $( $). Absolutely no type checking is
done. The definition of constant expression is extended
to include:

o address of static variable
o static array names
o function names
o "character string"

2. Aggregate types can be initialized by the following
construct:

$( init-element-1, init-element-2, ..., init-element-m $)

a. if fewer initializers than elements appear, the rest of
the aggregate is initialized to zero.

b. if the number of elements of an array is not specified,
then it will be set to the number of initializers.

c. a character array may be initialized by a string.

Examples:

int x = 23*22;

char *p = "hello";
char q[10] = "hello"; /* q[6] ... q[9] are set to '\0' */
```

```
int f();
int (*pf)() = f;

/* array bound set to 5 */
char *weekdays[] = $( "Mon", "Tues", "Wed", "Thu", "Fri" $);

struct x $(
char *symbol;
int value;
$);
struct x tab[] = $(
$( "word1", 4 $),
$( "word2", 8 $),
$( "word3", 13 $)
$);
```

Caveats:

local variables cannot be initialized (bad programming practice anyway)

GOTOS AND LABELS

CC8 suports the dreaded goto statement and labels. The compiler does not distinguish between labels and

ERROR HANDLING

Error messages are printed in the typical Unix C fashion:

file-name, line #: error message

In addition, the line causing the error is printed. Note: if the error occurs near the end of a line, the compiler will usually flag the next line.

This compiler, like DBC and ACE C, does not know how to intelligently recover from syntax errors. For this reason, the compiler will halt compilation after 8 errors.

The compiler no longer exits directly to DOS on fatal errors (e.g., too many errors) so that the user may jump directly to an editor using the command line feature described below.

I would appreciate knowing if the compiler hangs after finding an error or a certain sequence of errors.

INTERNAL LIMITS AND TABLE SIZES

Lest we forget this is not a 48K 8 bit implementation of C, here are some of the more important limits:

1. 7000 bytes of "global space" -- shared by:

- macro definitions
- each unique non-macro symbol name (15 bytes + length of symbol)
- global symbol type info

2. 256 bytes of "local space"

- local symbol type info
- only 128 local symbols may be declared.

3. A source line may not be longer than 254 characters after macro expansion. WARNING: this limit is not checked!

4. An expression cannot generate more than 512 bytes of p-code instructions. An expression violating this limit would be ridiculously huge. WARNING: this limit is not checked!

5. 512 bytes of "string space"

- This table was 3000 bytes in DBC and probably ACE C too.
- A way around the size constraint is to use initializers:

```
char dummy1[] = " ... ";
char dummy2[] = " ... ";
...
```

6. 2300 bytes of stack space

The compiler has been written to conserve stack space, so stack overflows should be a rarity. This is fortunate because -- WARNING: this limit is not checked! Stack overflow will overwrite screen memory (but it's possible the compile will complete normally).

7. #define macros may have up to 128 arguments.

CC8 uses memory from MEMLO to MEMTOP and locations $480 to $6FF. MEMLO must not exceed $2BFF.

SPEED

CC8 is much faster than DBC and slightly faster than ACE C (15% - 30% depending on type of program). Compilation time is affected most by the presence of #defines. You should expect compilation times of 15 to 30 seconds for small programs, and up to 2:00 for large programs with many #defines. Larger source files are possible, but run the risk of running out of internal table space. Some sample times:

Program Description	SC	ACEC	DBC
238 lines, no #defines	58	80 (1)	551
same, one #define	66 (2)	77 (1)	-
482 lines + 222 #include'd many #defines + comments	107	-	-

Note: these timings were made on an 800xl with a 1050 running DOS 2.5 with write verify on.

(1) I can't explain this anomaly.

(2) The reason one #define makes so much difference is that the compiler takes advantage of the zero #defines to skip part of the pre-

processing phase.

COMMAND LINE FEATURES

For users of DOS' that take a long time to reload (such as DOS 2.X), a way to load and run files directly from the command line has been provided.

o ^L<RETURN> runs file called "D1:LINK.COM"
o ^Lfilename<RETURN> runs file called "filename"
("D1:" and ".COM" default)
o ^E<RETURN> runs file called "D1:EDIT.COM"

Note this feature is in its infancy.

1. The control characters print as their equivalent graphic characters.

2. ^L runs the ACE C and DBC linkers, and ^E runs SpeedScript. Nothing else has been tested.

3. "Theoretically" the load routine understands INIT addresses.

MISCELLANEOUS

Switch statement handling has been reworked. The last clause need not end in "break", "continue", or "return". In addition, the "default" clause need not be the last (this was a bug in DBC). On the down side, you are limited to 100 "case"s per switch statement, and switch statements may be safely nested only four or five deep. I'll wait until someone complains before I attempt to fix this.

More efficient code is now generated for the && and || operators.

Local variables may be declared at the beginning (not just anywhere as in DBC) of compound statements. However no two local variables declared inside a function may have the same name (this is a departure from standard C). Variables declared with a storage class of "register" are the same as "auto".

All C reserved words are recognized by the compiler. Thus a variable cannot be named "float" or "entry."

Characters with the 8th bit set not part of character constants, strings, or comments will cause the compiler to crash.

FASTC.COM should work on CC8 output.

I have been told that the compiler also works with the LightSpeed C linker and runtime engine.

FUTURE

1. Improve error handling

2. Add ability to pass files to compile in command line for SpartaDOS and compatible DOS.

ACKNOWLEDGEMENTS

Thanks to Harald Striepe and Marc Appelbaum for their beta testing.

Thanks to Mark VandeWettering and Greg Koolbeck for their input.

540. 6502 upgrade for the atariS?

Newsgroup: comp.sys.atari.8bit
Date: 1987-09-08 22:35:00 UTC
From: DFLINT02@ULKYVX.BITNET
Message-ID: <8709082242.AA23091@ucbvax.Berkeley.EDU>
Source record: 117594

Hi John
Could you refer my questions to your resident Hardware wizard PauL
Swanson.

Has anyone out there ever tried to run the atari custom chips
at a higher clock rate. They normally run at 1.79Mhz but the cpu
can run at a full 2mhz.

I'm thinking about replacing the 6502 with the 65816(The IIGs cpu).
the 65816 can run at clock speeds between 1mhz and 4mhz.
I know that the 65816 is not directly pin compatable with the
Atari 6502c(Its in the Xl & XEs), but it should work thru the
parrallel bus.

Does anyone here in netland known of other 8/16 bit 6502 compatible
cpu's. Also price list and distributors of the 65816 compatibles
would be very helpful.

While talking to the "doctor" after my 800XL's recent brain
transplant, I also learned to my surprise that the CPU is not a stock
6502. I believe I was told that there is a small amount of extra
circuitry in there for address decoding, but am not sure. Can check
it out if you wish.

> number 1 above). Better yet, are there any "alternate OS" available for

For playing around with the OS, I suggest you get The Boss
alternate OS. In addition to being a good substitution for the
Translator disk, it offers coldstart from the keyboard, and has a
special mode where it deselects the OS ROM in favor of the RAM
underneath, and copies itself there. What you get is a RAM OS that
you can POKE around with.

542. CPU upgrades

Newsgroup: comp.sys.atari.8bit
Date: 1987-09-09 17:17:15 UTC
From: ehs@jumbo.dec.com
Message-ID: <923@jumbo.dec.com>
Source record: 117596

Several recent postings have raised questions about CPU upgrades for the 8 bit Ataris. The obvious candidates are the 65C02, a CMOS version of the 6502 with some minor extensions, and the 65802, a version of the 65816 (Apple IIgs CPU) that is pin compatible with the 6502. One source of both is Jameco Electronics; see any issue of Byte, etc., for their ads. The most recent prices I've seen are
65C02: $8.95
65C802 $19.95
To keep things in perspective, Jameco's quantity-one prices for the 68000 range from $11.95 (8 MHz) to $17.95 (12 MHz); i.e., neither 6502 replacement is much of a bargain in terms of processing power, especially considering the relative amount of support available.

For a while, I thought that upgrading my 800 with one of these would be really nifty. I think I was wrong. Maybe I'm overlooking something, but here's how I see things:

(1) Software

The 65C02 includes a few new opcodes that plug a number of annoying holes in the 6502 instruction set. The MAC/65 assembler for the Atari supports these extensions, so anything for which I have assembler source could be (re)written to take advantage of them. But most of the software I care about was either bought on the commercial market or written in Action. No gain there (or for Basic either).

To my knowledge, the only commercial assemblers that support the 65802/65816 extensions run on the Apple II line of machines. So the situation there is even bleaker.

In either case, I couldn't give or sell my software to owners of vanilla Ataris -- or to Apple IIc/e/gs owners either.

(2) Speed

I just glanced through the Rockwell data book (only one at hand covering the 6500). The tabulated cycles/instruction are essentially identical for the R6502 and R65C02. In fact, their 65C02 is a cycle *slower* on decimal arithemetic (as in Basic floating point). I think I recall reading that the WDC (= NCR?) 65C02 did shave a cycle here and there, but that the speedups were removed in the WDC 65802/65816 running in compatibility mode, presumably so that old timing loops would work. No significant gain here without changing the clock speed.

But changing the clock speed will almost certainly cause major problems with everything else. The 1.79 MHz. crystal was chosen to match a color TV standard, not because the processor won't go faster. In fact, at least

some 800's were built with 6502B's, which are rated to run at 3MHz.

(3) Power

The new CMOS chips do use less, but I don't believe that the old NMOS 6502 is consuming any significant amount of the power used by an Atari 8-bitter.

(4) Wider Bus

The 65816 brings out more address lines and thus visions of big memories without bank switching, etc. Someone who chooses to stuff all this in an old Atari box might have a lot of fun and learn a lot, but he ought to understand that he is basically engineering a whole computer system, and probably much of its software, from scratch.

I'd appreciate comments and counterarguments; I'd still love an excuse to try the upgrades.

> Thanks in advance.....

Best Electronics advertises in the Puget Sound Atari Newsletter
a kit with instructions for a do-it-yourself upgrade to your
600xl. They are:

Best Electronics
2021 The Alameda
Suite 290
San Jose, CA. 95126
(408)243-6950

They have a 64k upgrade for $15, and for $28 you can get a 256k mod
which was designed by Jeff Popp in Redmond Wash.

American Techna-vision, at 1-800-551-9995, has a 64k plug-in
module for 29.95, but they didn't sound very encouraging about 256k.

I would like to know what the pinout of the 1200xl's port b is. also,
which pin on the 6520 corresponds to bit 0 (I assume the rest are meerly
increments of bin and bit). Also, there have been some rumors on
occasion that the CPU in the Atari 8 bitters is a custom CPU with a 6502
instruction set. Is this true? If so, what changes were made? I have
a 65C802 CPU (16 bit, 6502 pin compatible) that I would like to drop
into my 1200 or 130XE. A friend has done this with a Vic-20 (no laughs
please) and had no problems...except his games sped up. Comments and
suggestions are welcome.

From: Cothrell@DOCKMASTER.ARPA
Subject: 1200xl and the cpu and OSe
To: info-atari8@SCORE.STANFORD.EDU

Ok, I have just found out that the 1200xl (and I presume everything else
but the 400 and 800) does NOT have a standard 6502 in it. Can anyone
answere the questions of the day? Namely, what was done to the
processor to make it non-standard? I suspect that the boot vector (as
well as some others) have been changed from the standard 6502 vectors.
If you dont know for sure, but could tell me how to talk to somebody at
Atari...I would appreciate that greatly. Otherwise, suggestions and
comments are welcome...results will be posted (if there are any). The
second question concerns the OS source code. Has the OS source been
published for the xl/xe machines (i have a 1200xl and a 130xe). If it
has been published, who and where??? If not...does anyone have a
suggestion for writing an OS? I want to use a regular 6502 in my 1200xl
and I think I will need to change the OS startup vectors (see question
number 1 above). Better yet, are there any "alternate OS" available for
the ataris...and would any of the authors be willing to release the
source under a non-disclosure agreement or make a custom version?

please address replies to Cothrell -at DOCKMASTER.ARPA or to Info-Atari8
thanks...Scott Cothrell Cothrell -at DOCKMASTER.ARPA.

From: cbosgd!cbterra!smk@ucbvax.Berkeley.EDU (Stephen Kennedy)
Subject: CC8 Compiler Version 2.3b (1 of 3)
To: info-atari8@score.stanford.edu

This is version 2.3b of CC8, an improved version of the Deep Blue C Compiler. The version fixes a particularly nasty bug found by John Dunning (#4 below) and has some other differences from the original posted version (detailed below).

Part 1 -- this article
Part 2 -- the original CC8 doc
Part 3 -- the uuencoded CC8.COM (33732 bytes, 24465 bytes uudecoded)

Steve Kennedy {ihnp4,moss,decwrl,?}!cbosgd!smk

[CC8 is available for FTPing from SCORE::<INFO-ATARI>CC8.NTXT (in tops20 mail file (eg text) format). --BillW]

The following is a list of fixed bugs, enhancements, and known problems:

Bug fixes:

1. Empty expressions in for statement accepted, i.e.,

for(;;;) $($)

2. Constant expression are now valid after "case", i.e., "case 2*3." (fixes "case -1:" problem)

3. "*a" if a is an array no longer generates an error.

4. A function argument declaration of "type var[]" is now converted to "type *var." Previously, the compiler generated bad code which caused a lock-up when the resulting program was run (e.g., programs using "getname()" in ACECIO.C).

Enhancements:

1. The expressions "a[x]" and "x[a]" are both valid and equivalent provided one of x or a is a pointer or array.

2. structs without explicit tag names are now legal, i.e.,

"struct $(.... $) y;"

3. The compiler now recognizes the keywords "short" and "long." Note that "int" = "short" = "short int" = "long" = "long int" = 2 bytes. "Long" declarations produce the warning "long == short."

4. The compiler now recognizes the keyword "unsigned" and will generate unsigned comparison code for <, <=, >, or >=

when one or both operands are unsigned.

Caveats:

- You'll have to write your own routines to print these
correctly (no %u in ACE C or DBC printf).

- I'm not sure *, /, or % work properly on unsigned numbers.

Known problems (send mail or post if you want to add to the list):

1. Not all escape sequences recognized by ACE C are recognized by
CC8. (\u, \d, \l, \r, \e)

2. Compiler doesn't like "register x" although it will accept
"register int x." Note that "register" doesn't do anything
special anyway.

To: Info-atari8@SCORE.STANFORD.EDU

I would like to know what the pinout of the 1200xl's port b is. also,
which pin on the 6520 corresponds to bit 0 (I assume the rest are meerly
increments of bin and bit). Also, there have been some rumors on
occasion that the CPU in the Atari 8 bitters is a custom CPU with a 6502
instruction set. Is this true? If so, what changes were made? I have
a 65C802 CPU (16 bit, 6502 pin compatible) that I would like to drop
into my 1200 or 130XE. A friend has done this with a Vic-20 (no laughs
please) and had no problems...except his games sped up. Comments and
suggestions are welcome.

From: Cothrell@DOCKMASTER.ARPA
Subject: 1200xl and the cpu and OSe
To: info-atari8@SCORE.STANFORD.EDU

Ok, I have just found out that the 1200xl (and I presume everything else
but the 400 and 800) does NOT have a standard 6502 in it. Can anyone
answere the questions of the day? Namely, what was done to the
processor to make it non-standard? I suspect that the boot vector (as
well as some others) have been changed from the standard 6502 vectors.
If you dont know for sure, but could tell me how to talk to somebody at
Atari...I would appreciate that greatly. Otherwise, suggestions and
comments are welcome...results will be posted (if there are any). The
second question concerns the OS source code. Has the OS source been
published for the xl/xe machines (i have a 1200xl and a 130xe). If it
has been published, who and where??? If not...does anyone have a
suggestion for writing an OS? I want to use a regular 6502 in my 1200xl
and I think I will need to change the OS startup vectors (see question
number 1 above). Better yet, are there any "alternate OS" available for
the ataris...and would any of the authors be willing to release the
source under a non-disclosure agreement or make a custom version?

please address replies to Cothrell -at DOCKMASTER.ARPA or to Info-Atari8
thanks...Scott Cothrell Cothrell -at DOCKMASTER.ARPA.

To: info-atari8@score.stanford.edu
X-Original-To: info-atari8@score.stanford.edu

Hi John
Could you refer my questions to your resident Hardware wizard PauL
Swanson.

Has anyone out there ever tried to run the atari custom chips
at a higher clock rate. They normally run at 1.79Mhz but the cpu

can run at a full 2mhz.

I'm thinking about replacing the 6502 with the 65816(The IIGs cpu).
the 65816 can run at clock speeds between 1mhz and 4mhz.
I know that the 65816 is not directly pin compatable with the
Atari 6502c(Its in the Xl & XEs), but it should work thru the
parrallel bus.

Does anyone here in netland known of other 8/16 bit 6502 compatible
cpu's. Also price list and distributors of the 65816 compatibles
would be very helpful.

While talking to the "doctor" after my 800XL's recent brain
transplant, I also learned to my surprise that the CPU is not a stock
6502. I believe I was told that there is a small amount of extra
circuitry in there for address decoding, but am not sure. Can check
it out if you wish.

For playing around with the OS, I suggest you get The Boss
alternate OS. In addition to being a good substitution for the
Translator disk, it offers coldstart from the keyboard, and has a
special mode where it deselects the OS ROM in favor of the RAM
underneath, and copies itself there. What you get is a RAM OS that
you can POKE around with.

From: cbosgd!cbterra!smk@ucbvax.Berkeley.EDU (Stephen Kennedy)
Subject: CC8 Compiler Version 2.3b (1 of 3)
To: info-atari8@score.stanford.edu

This is version 2.3b of CC8, an improved version of the Deep Blue C Compiler. The version fixes a particularly nasty bug found by John Dunning (#4 below) and has some other differences from the original posted version (detailed below).

Part 1 -- this article
Part 2 -- the original CC8 doc
Part 3 -- the uuencoded CC8.COM (33732 bytes, 24465 bytes uudecoded)

Steve Kennedy {ihnp4,moss,decwrl,?}!cbosgd!smk

[CC8 is available for FTPing from SCORE::<INFO-ATARI>CC8.NTXT (in tops20 mail file (eg text) format). --BillW]

The following is a list of fixed bugs, enhancements, and known problems:

Bug fixes:

1. Empty expressions in for statement accepted, i.e.,

for(;;;) $($)

2. Constant expression are now valid after "case", i.e., "case 2*3." (fixes "case -1:" problem)

3. "*a" if a is an array no longer generates an error.

4. A function argument declaration of "type var[]" is now converted to "type *var." Previously, the compiler generated bad code which caused a lock-up when the resulting program was run (e.g., programs using "getname()" in ACECIO.C).

Enhancements:

1. The expressions "a[x]" and "x[a]" are both valid and equivalent provided one of x or a is a pointer or array.

2. structs without explicit tag names are now legal, i.e.,

"struct $(.... $) y;"

3. The compiler now recognizes the keywords "short" and "long." Note that "int" = "short" = "short int" = "long" = "long int" = 2 bytes. "Long" declarations produce the warning "long == short."

4. The compiler now recognizes the keyword "unsigned" and will generate unsigned comparison code for <, <=, >, or >=

when one or both operands are unsigned.

Caveats:

- You'll have to write your own routines to print these
correctly (no %u in ACE C or DBC printf).

- I'm not sure *, /, or % work properly on unsigned numbers.

Known problems (send mail or post if you want to add to the list):

1. Not all escape sequences recognized by ACE C are recognized by
CC8. (\u, \d, \l, \r, \e)

2. Compiler doesn't like "register x" although it will accept
"register int x." Note that "register" doesn't do anything
special anyway.

From: jumbo!ehs@decwrl.dec.com (Ed Satterthwaite)
Subject: CPU upgrades
To: info-atari8@score.stanford.edu

Several recent postings have raised questions about CPU upgrades for the 8
bit Ataris. The obvious candidates are the 65C02, a CMOS version of the
6502 with some minor extensions, and the 65802, a version of the 65816
(Apple IIgs CPU) that is pin compatible with the 6502. One source of both
is Jameco Electronics; see any issue of Byte, etc., for their ads. The
most recent prices I've seen are
65C02: $8.95
65C802 $19.95
To keep things in perspective, Jameco's quantity-one prices for the 68000
range from $11.95 (8 MHz) to $17.95 (12 MHz); i.e., neither 6502
replacement is much of a bargain in terms of processing power, especially
considering the relative amount of support available.

For a while, I thought that upgrading my 800 with one of these would be
really nifty. I think I was wrong. Maybe I'm overlooking something, but
here's how I see things:

(1) Software

The 65C02 includes a few new opcodes that plug a number of annoying holes
in the 6502 instruction set. The MAC/65 assembler for the Atari supports
these extensions, so anything for which I have assembler source could be
(re)written to take advantage of them. But most of the software I care
about was either bought on the commercial market or written in Action. No
gain there (or for Basic either).

To my knowledge, the only commercial assemblers that support the
65802/65816 extensions run on the Apple II line of machines. So the
situation there is even bleaker.

In either case, I couldn't give or sell my software to owners of vanilla Ataris -- or to Apple IIc/e/gs owners either.

(2) Speed

I just glanced through the Rockwell data book (only one at hand covering the 6500). The tabulated cycles/instruction are essentially identical for the R6502 and R65C02. In fact, their 65C02 is a cycle *slower* on decimal arithemetic (as in Basic floating point). I think I recall reading that the WDC (= NCR?) 65C02 did shave a cycle here and there, but that the speedups were removed in the WDC 65802/65816 running in compatibility mode, presumably so that old timing loops would work. No significant gain here without changing the clock speed.

But changing the clock speed will almost certainly cause major problems with everything else. The 1.79 MHz. crystal was chosen to match a color TV standard, not because the processor won't go faster. In fact, at least some 800's were built with 6502B's, which are rated to run at 3MHz.

(3) Power

The new CMOS chips do use less, but I don't believe that the old NMOS 6502 is consuming any significant amount of the power used by an Atari 8-bitter.

(4) Wider Bus

The 65816 brings out more address lines and thus visions of big memories without bank switching, etc. Someone who chooses to stuff all this in an old Atari box might have a lot of fun and learn a lot, but he ought to understand that he is basically engineering a whole computer system, and probably much of its software, from scratch.

I'd appreciate comments and counterarguments; I'd still love an excuse to try the upgrades.

547. Custom 6502

Newsgroup: comp.sys.atari.8bit
Date: 1987-09-10 15:17:00 UTC
From: Cothrell@DOCKMASTER.ARPA
Message-ID: <870910151738.120389@DOCKMASTER.ARPA>
Source record: 117601

jwt at Atari has written me a note stating that the CPU in the later Atari computers (everything but the 800/400 I guess) is indeed custom. The difference seems to be that the custom chip has the ability to tri-state its 'bus'. I have asked for clarification of its 'bus', but I think that he means the address bus (at least) and possibly more. Apparently the old 800's had the tri-state logic external to the 6502.

Ed Satterthwaite raised the point of the "worthwhileness" of attempting to replace the cpu in the atari computers. I agree that most of his points are logical and reasonable. That doesn't change my mind, I just happen to agree with him. (I am a hacker at heart and sanity has never been a prerequisite)

I happen to have the 800 schematics which show the tri-state logic (if you want to call it that...weirdest contraption I ever saw...anyone know the reasoning behind that design??? I though one used the 650X because the phased clocks were generated for you!) and am going to try to make a "processor module" that will drop into the custom 6502 socket and properly tri-state things.

wish me luck (I'll probably need it)

Scott Cothrell

Source record: 117603

Unfortunately, there is nothing to differentiate between 8 bit
and 16 bit programs in <info-atari>. Almost all files are in
there original mail-message format, and must be cut, pasted,
uudecoded, and de-arced by hand. *.N* are files that have been
received but never sent out to the net. Other files are older
and may have been sent in some number of pieces soon after
there original postings. Some files contain multiple versions
of the same program, some files have peices missing. I may
actually get araound to distributing atari8 programs to the net
via mail, but the volume of normal mail (and the size of programs)
for the atari16 list makes this completely impossible.

I assume that the custom 6502 tri-states its address bus when the Antic puts pin 9 (HALT) low. I think I have further deduced that pin 35 of the 6502 is the trigger for the tri-stating. two questions. am I right so far, and is the data bus also tri-stated? thanx,

Scott Cothrell

A couple people have found out (somehow?!) already and since
this question was brought up I might as well mention that I
have already been working on the 200% Turbo XL.

The 6502 in the XL ("Sally") is, as was sumarized, a 6502
with tri-state buffering. When a chip goes tri-state, it
becomes electronically transparent. Antic tri-states the 6502
so that it doesn't react when Antic starts accessing memory.

The 400/800 (and the TRS-80 for that matter) had tri-state
buffers on the board. To lower the chip count on the XL line,
Atari made a custom 6502 that moves those buffers into the
CPU.

We have long known/required a socket that would simply externalize
those buffers so as to make a path for the XL/XEs take a
65802/65C02. ActuallyI don't care what you put in it as long
as it's pin compatible and runs 4 Mhz. This socket is indeed
a possibilty, I've just been too busy messing with the rest of
the timing considerations.

Mathematically computed benchmarks of the Turbo XL show it runs
quite favorably with the IBM PC, Mac, and (suprise!) ST. This
was borne out to some extent with the release of the turbo-
upgrade for the C64.

I have no plans for attempting a 16-bit version of the mod.
Granted the 64 mod is, but I am planning this mod to be along
the lines of the 256/320 XL/XE memory upgrades. Something
that many can make, easily. The memory upgrade is great, and
I strongly reccommend it to anyone who does anything other than
play Pacman.

Please dont ask major techincal details, since I'd like to
make a little money from the efforts on this. By no means do
we intend on letting this mod cost more than $50. If it
gets
that way, then it gets to be PD.

Terry Conklin (and, actually, partner in crime Ken Sumrall)

I still can't believe I'm reading this. You mean to say I'll soon be able to purchase an upgrade that will double the speed of my 800XL? Hot diggedy!

Only a few general questions: When? Where? Major caveats of the increased clock speed? (That is, will all software run?) Will there be a hard or software switch to bring the speed down to normal if desired?

If this proposal becomes a reality, you will indeed "make a little money" from the efforts.

Custom 6502
File Format of <info-atari>
Re: File Format of <info-atari>
Re: 600XL Upgrade to 256k ? Where and How?
custom 6502

------------------------------------------------------------------------

Date: Thu, 10 Sep 87 11:17 EDT
From: Cothrell@DOCKMASTER.ARPA
Subject: Custom 6502
To: info-atari8@SCORE.STANFORD.EDU

jwt at Atari has written me a note stating that the CPU in the later
Atari computers (everything but the 800/400 I guess) is indeed custom.
The difference seems to be that the custom chip has the ability to
tri-state its 'bus'. I have asked for clarification of its 'bus', but I
think that he means the address bus (at least) and possibly more.
Apparently the old 800's had the tri-state logic external to the 6502.

Ed Satterthwaite raised the point of the "worthwhileness" of attempting
to replace the cpu in the atari computers. I agree that most of his
points are logical and reasonable. That doesn't change my mind, I just
happen to agree with him. (I am a hacker at heart and sanity has never
been a prerequisite)
```

I happen to have the 800 schematics which show the tri-state logic (if you want to call it that...weirdest contraption I ever saw...anyone know the reasoning behind that design??? I though one used the 650X because the phased clocks were generated for you!) and am going to try to make a "processor module" that will drop into the custom 6502 socket and properly tri-state things.

wish me luck (I'll probably need it)

Subject: Re: File Format of <info-atari>
To: Cothrell@DOCKMASTER.ARPA
In-Reply-To: <870910153256.454558@DOCKMASTER.ARPA>

Unfortunately, there is nothing to differentiate between 8 bit and 16 bit programs in <info-atari>. Almost all files are in there original mail-message format, and must be cut, pasted, uudecoded, and de-arced by hand. *.N* are files that have been received but never sent out to the net. Other files are older and may have been sent in some number of pieces soon after there original postings. Some files contain multiple versions of the same program, some files have peices missing. I may actually get araound to distributing atari8 programs to the net via mail, but the volume of normal mail (and the size of programs) for the atari16 list makes this completely impossible.

Best Electronics advertises in the Puget Sound Atari Newsletter
a kit with instructions for a do-it-yourself upgrade to your
600xl. They are:

Best Electronics
2021 The Alameda
Suite 290
San Jose, CA. 95126
(408)243-6950

They have a 64k upgrade for $15, and for $28 you can get a 256k mod
which was designed by Jeff Popp in Redmond Wash.

American Techna-vision, at 1-800-551-9995, has a 64k plug-in
module for 29.95, but they didn't sound very encouraging about 256k.

APEX is dead. ANTIC has taken over a major portion of their catalog, but
I remember that in their catalog in the middle of their magazine it was
noted that the CHAMELEON stock was getting low.

John Dunning's K65 posted on this net contains the best VT100 emulator so
far, and also includes VT52 emulation.
You have a choice of scrolling 40 columns, or 80 columns in GR.8 mode using
fairly legible 4 bit cells.

556. Re: 1200xl and the cpu and OSe

Newsgroup: comp.sys.atari.8bit
Date: 1987-09-15 22:55:37 UTC
From: hans@umd5.umd.edu
Message-ID: <1935@umd5.umd.edu>
Source record: 117410

The XL and XE systems, as well as some 400s (maybe all), have a 6502C cpu chip. Its main distinction is the fact that it can tri-state the address bus, a feature which none of the standard 6500 family chips have.

I recall reading that there is a chip in the 65c00 family which does have the tri-state feature (maybe 65c11), but have no information as to whether its pinout is compatible with the Atari chip.
Being somewhat non-standard, it might also be considerably more expensive or harder to find.

As far as I know there are no programming differences between the 6502 and the 6502c.

As far as souping up the XL with a faster cpu, I have two concerns:
1. coordinating a faster cpu and the standard Antic might be quite a challenge. You would need memory which can run at slow and fast cycle rate, depending on who is talking to it. And while there is a fair amount of slack in memory timing with the current design, a significant speedup might cause much difficulty.
2. The i/o bandwidth is about 1920 bytes/second, and unless you main goal is to compute prime numbers, or do Mandelbrot pictures, any speedup is likely to make the i/o restrictions seem even more painful. Of course you might have disks on an MIO or similar device, but then you need to re-visit the first point I made.

557. 65C802 processor card.

Newsgroup: comp.sys.atari.8bit

Source record: 117411

thanks for all the responses to my questions concerning the cpu in the later versions of the atari. to summarize the responses: 1. the CPU is indeed custom. 2. the custom part is internal to the 6502 and is responsible for tri-stating the address bus.

3. the "new" 6502 has pin 35 defined as "tri-state the bus" 4. everything else about the cpu appears to be standard 6502.

now for my observations...

I have built 2 processor cards(they drop into the cpu socket of my 1200xl), one with the circuitry of the old 800(from schematics) and one with a design of my own. Neither works...and I don't know why. I suspect the tri-state signal from the ANTIC. I have successfully duplicated/generated the bi-phase clock as well as the other circuitry. One of the potential problems is the wishy-washy signal levels I am getting(and generating) from the rest of the circuitry. the normal clock levels seem to be symetric about 1.25 V. The rest of the system seems to be little better. (the clocks have a swing of about .5V p-p) Perhaps the Atari chips are CMOS??? I dont know. The tri-state signal(HALT) from the ANTIC is by far the weirdest signal I have seen in digital electronics(ever!). Perhaps my scope is picking up harmonics or something, but I swear that the signal has at least 4 parts, one of which registers on my scope as a +5 flat-line. there are some high speed digital signals that register CLEARLY under the +5v with enough swing to definitely be on/off cycles. If anybody else can take a scope to their atari, check out pin 9 of the ANTIC or 35 of the CPU. I know that I am at the upper limit of my porta-scope when looking at that signal, but I can see enough to make me wonder just what all the activity is about. (just to be sure, I tried it on ac and dc couple, same picture). Anyway, they circuitry for the 800 seems to produce the cleanest signals, so I am saving that circuit...suggestions as to fixes, etc... are welcome.

560. The 6502 difference

Newsgroup: comp.sys.atari.8bit
Date: 1987-09-16 16:01:01 UTC
From: pkopp@potpourri.UUCP
Message-ID: <607@potpourri.UUCP>
Source record: 117414

This was posted on the net a while back. I saved this because I knew I would need it someday.

Apparently the so called "6502" used in the Atari's is a custom modified chip, hence its not using the industry type JDEC number. From Mike at Xerox comes the following:

Atari 6502c #C014806 standard 6502

pin no. function pin no. function
36 READ/WRITE 36 N.C.
35 /HALT 35 N.C.
34 N.C. 34 READ/WRITE

Therefore one could bend up pins 34 and 36 and do a wire connection to swap these two pins, but that would still leave you without a /HALT command. (Presumably the halt command is necessary.) I do not know if the 6502c chip used by Atari is identical between the original 400/800, the intermediate XL series and the current XE series.

APEX is dead. ANTIC has taken over a major portion of their catalog, but I remember that in their catalog in the middle of their magazine it was noted that the CHAMELEON stock was getting low.

John Dunning's K65 posted on this net contains the best VT100 emulator so far, and also includes VT52 emulation.
You have a choice of scrolling 40 columns, or 80 columns in GR.8 mode using

fairly legible 4 bit cells.

Subject: Re: 1200xl and the cpu and OSe
To: info-atari8@score.stanford.edu

The XL and XE systems, as well as some 400s (maybe all), have a 6502C cpu chip. Its main distinction is the fact that it can tri-state the address bus, a feature which none of the standard 6500 family chips have.

I recall reading that there is a chip in the 65c00 family which does have the tri-state feature (maybe 65c11), but have no information as to whether its pinout is compatible with the Atari chip.
Being somewhat non-standard, it might also be considerably more expensive or harder to find.

As far as I know there are no programming differences between the 6502 and the 6502c.

As far as souping up the XL with a faster cpu, I have two concerns:
1. coordinating a faster cpu and the standard Antic might be quite a challenge. You would need memory which can run at slow and fast cycle rate, depending on who is talking to it. And while there is a fair amount of slack in memory timing with the current design, a significant speedup might cause much difficulty.
2. The i/o bandwidth is about 1920 bytes/second, and unless you main goal is to compute prime numbers, or do Mandelbrot pictures, any speedup is likely to make the i/o restrictions seem even more painful. Of course you might have disks on an MIO or similar device, but then you need to re-visit the first point I made.

The closest one is probably B.A.C.E., which stands for I dunno what but their address is:

B.A.C.E.
Paul Freeman

6502 Smokehouse Court (neat address, eh?!)
Columbia MD 21045

Paul's phone number is (301) 381-6642. This group has over 60 PD disks available, charges about $1 per disk plus some postage.

Another useful one is Novatari, the Northern Virginia Atari Users' Group, c/o Earl Lilley, 821 Ninovan Road, Vienna, VA 22180. They charge about $3 per disk plus $1 per 3 disks to cover postage. They also publish a very worthwhile newlsetter called Current Notes.

From: Cothrell@DOCKMASTER.ARPA
Subject: 65C802 processor card.
To: info-atari8@SCORE.STANFORD.EDU

thanks for all the responses to my questions concerning the cpu in the later versions of the atari. to summarize the responses: 1. the CPU is indeed custom. 2. the custom part is internal to the 6502 and is responsible for tri-stating the address bus.

3. the "new" 6502 has pin 35 defined as "tri-state the bus" 4. everything else about the cpu appears to be standard 6502.

now for my observations...

I have built 2 processor cards(they drop into the cpu socket of my 1200xl), one with the circuitry of the old 800(from schematics) and one with a design of my own. Neither works...and I don't know why. I suspect the tri-state signal from the ANTIC. I have successfully duplicated/generated the bi-phase clock as well as the other circuitry. One of the potential problems is the wishy-washy signal levels I am getting(and generating) from the rest of the circuitry. the normal clock levels seem to be symetric about 1.25 V. The rest of the system seems to be little better. (the clocks have a swing of about .5V p-p) Perhaps the Atari chips are CMOS??? I dont know. The tri-state signal(HALT) from the ANTIC is by far the weirdest signal I have seen in digital electronics(ever!). Perhaps my scope is picking up harmonics or something, but I swear that the signal has at least 4 parts, one of which registers on my scope as a +5 flat-line. there are some high speed digital signals that register CLEARLY under the +5v with enough swing to definitely be on/off cycles. If anybody else can take a scope to their atari, check out pin 9 of the ANTIC or 35 of the CPU. I know that I am at the upper limit of my porta-scope when looking at that signal, but I can see enough to make me wonder just what all the activity is about. (just to be sure, I tried it on ac and dc couple, same picture). Anyway, they circuitry for the 800 seems to produce the cleanest signals, so I am saving that circuit...suggestions as to fixes,

etc... are welcome.

Subject: The 6502 difference
To: info-atari8@score.stanford.edu

This was posted on the net a while back. I saved this because I knew I
would need it someday.

Apparently the so called "6502" used in the Atari's is a custom modified
chip, hence its not using the industry type JDEC number. From Mike at Xerox
comes the following:

Atari 6502c #C014806 standard 6502

pin no. function pin no. function
36 READ/WRITE 36 N.C.
35 /HALT 35 N.C.
34 N.C. 34 READ/WRITE

Therefore one could bend up pins 34 and 36 and do a wire connection to swap
these two pins, but that would still leave you without a /HALT command.
(Presumably the halt command is necessary.) I do not know if the 6502c
chip used by Atari is identical between the original 400/800, the intermediate
XL series and the current XE series.

567. 6502 stuff

Newsgroup: comp.sys.atari.8bit
Date: 1987-09-22 00:43:00 UTC
From: Cothrell@DOCKMASTER.ARPA
Message-ID: <870922004320.315453@DOCKMASTER.ARPA>
Source record: 117421

Mike B. (this is being sent to two accounts, Dflint02 at ulkyvx.bitnet
and cl150652 at ulkyvm.bitnet)

I sent something similar to this out to info-atari8, so if you've seen
it, read it anyway. (just kidding). I used the circuitry from the 800
tech ref book to do the tri-stating. I have it working as of
yesterday(20th) for the 6502(standard). It does not work with the
65C802 (802), I think due to the fact that the 800 "halts" the 6502 by
stretching the phase 0 clock at a logic 0 level. I don't know wether
you caught it or not, but the 800 did not use the phase 1 and 2 clocks
generated by the 6502...instead, a 7474 was used to generate the system
clocks externally(so when the phase 0 clock was stretched, it would not
affect the rest of the system). Anyway, the '802 cannot be "halted" by
stretching the phase 0 clock low...it has a maximum low time of 10 uS
and a max high time of infinity--just about opposite of the standard
6502. For that matter, the 65C01 and 65C02 have the same problem. I
have tried several ways of stretching the phase 0 clock at a logic 1
level, but to no avail, I think it throws the internal timing of the cpu
off. I might be able to make it work if I design a bit of circuitry,
which is what I am thinking about now, but am not having any luck(plus I
need a proto-board to do all this on...wire-wrap is a bitch).

about increasing the speed...been thinking about that too. My data book
(ala Synertek, 1983) shows 6502 available to 4 Mhz, 6520 to 2Mhz. In
looking at the 800 schematics, it has occurred to me that the board I
have built is the first step to building a faster processor. My
reasoning is as follows: We want to speed up the CPU without affecting
the rest of the circuits(ANTIC, GTIA, etc), so we will have to generate
the system clocks(Ph1 & Ph2) off of the CPU. Next, we have to be able
to stop the processor for ANTIC DMA. To stop the processor, in sync
with the ANTIC, we need use the "halt" signal of the ANTIC and have some
relationship between the ANTIC's master Ph0 and the CPU's Ph0. Next,
the system clocks Ph1 and Ph2 have to have "two speeds", one fast speed
for the CPU to do memory access, and a slow speed for the ANTIC etc...
.

What I have in mind(warped as it is) is using the Antic Ph0 as a trigger
to what I call a clock doubler, which will produce 2 Ph0 clock cycles
for each Antic Ph0 pulse. The doubled clock is basically the CPU Ph0.
For the system clocks, the best Idea I have right now is to run a 7474
(ala 800) at the doubled speed, providing the fast system clocks, and
putting a divide by two circuit in to make the ANTIC and GTIA slow
system clocks. The problem that I haven't got a solution for is the
actual memory accesses...how to have both fast and slow access...I think
I need a 6502 wait state??? but I dont know how to implement that just

yet.

To sum up these ramblings, the 65C802 project is at an stand-still for the moment. Until I figure out a way around the difference between the two processors I cant do much more but listen to the 1200xl doing sound checks with the standard 6502 board. Suggestions are solicited. CPU speedup seems like it might be possible, but I'm not going to be working on it anytime soon, I think someone out there already mentioned that he was close to a solution; it would be nice to here his comments and how he attacked the problem. Any comments from the Atari Inc. people on what their users are trying to do to their machines???

Any one get the ANALOG 8-bit Extra? I did
and typed in a program called CGM. I used
the MLEditor they supply. The MLEditor
doesn't allow you to make mistakes so
the program must be bad. The tracker
routines work just fine. But the windowing
causes a lock up. Actually the open window
is the lock up. If anyone out there has
a delphi password, did ANALOG put up the
corrected version yet? Anyone else have
this problem?

Tom

I just installed my new US Doublers and started using SpartaDos. Unfortunately SpartaDos conflicts with my OmniView 256 chip. This disables a few functions of SpartaDos that I would realy like to use.

Is there any easy way to make a "ramrod xl" card that that will allow me to choose between OmniView and the original OS?

Can I make a board that sockets both chips and put a switch to the +5 lines to activate the right chip at power up?
Do I need to worry about the ground wires? Can it be that simple?

I would appreciate hearing from anyone that owns a Ramrod board, or has any ideas.

The "world's record" for a 6502 is 24 Mhz (it was a one-of-a-kind
chip). With today's technology (the 6502 is about ten years old)
you could make 32 Mhz versions.

Put that in your '386 and smoke it!

Subject: SYSTEM FOR SALE
To: info-atari8@score.stanford.edu

My friend is selling his system which includes the following:

one 800 computer
one 800XL computer
one 1050 disk drive
one Indus GT disk drive
one voice box
one MPP-1000C 300 baud modem
joysticks
roughly 60 disks
miscellaneous cartridges
```

This system is between 1 and 4 years old (depending on piece).
Everything works. 800XL has a slight "rolling" problem. Everything
is unmodified.

My friend is moving and has no room to move the stuff...He will pay
for shipping...Prefer to sell as system, will separate if necessary...

Please send e-mail with a price to me.

From: "Gene Merritt" <F1.GDM%ISUMVS.BITNET@wiscvm.wisc.edu>

I just installed my new US Doublers and started using SpartaDos. Unfortunately SpartaDos conflicts with my OmniView 256 chip. This disables a few functions of SpartaDos that I would realy like to use.

Is there any easy way to make a "ramrod xl" card that that will allow me to
choose between OmniView and the original OS?

Can I make a board that sockets both chips and put a switch to the +5 lines to
activate the right chip at power up?
Do I need to worry about the ground wires? Can it be that simple?

I would appreciate hearing from anyone that owns a Ramrod board, or has any
ideas.

Subject: ANALOG 8-bit Extra
To: info-atari8@score.stanford.edu

Any one get the ANALOG 8-bit Extra? I did
and typed in a program called CGM. I used
the MLEditor they supply. The MLEditor
doesn't allow you to make mistakes so
the program must be bad. The tracker
routines work just fine. But the windowing
causes a lock up. Actually the open window
is the lock up. If anyone out there has
a delphi password, did ANALOG put up the
corrected version yet? Anyone else have
this problem?

572. reasons for upgrade!

Newsgroup: comp.sys.atari.8bit
Date: 1987-09-24 22:01:00 UTC
From: DFLINT02@ULKYVX.BITNET.UUCP
Message-ID: <8709242218.AA05629@ucbvax.Berkeley.EDU>
Source record: 117426

Did someone on the net ask for reasons on why an upgrade for the atari 6502
should be attempted.

Reasons for an upgrade to a 65816:

Upgrades in general tend to focus attention to computers, thus the
mega STs were born. A more powerful processor in our venerable 8-bits
would draw great attention from those who put their atari's on the shelf
So they could use/(play games on) c-64'S).

The apple came out with the apple IIgs which has the 65816 in it. This
addition of the horsepower attracted new interest to venerable 8-bit line.
Chances are it will do the same for ATARI. Since more atari xe/xl
machines exist than IIgs mabye some of the companys that wrote software
for the IIgs might try to recover there loses by writing software for
a machine which a potentially larger user base. Porting Apple software
to the atari shouldn't be to hard, tho the IIGs call would have to be
emulated.

If atari designed such an upgrade
they would not have to much trouble
get 65816 software developers? Some
one has mentioned that Mac65(which
is no longer in production) can
support the extra 6502 commands this
chips supports.

The main reason i would want a 65816 in my machine would be to embarrass
TRAMIAL. He has bumbled with a great machine. The handling of the 8-bit as
compared for the ST has been unexcusable. Atari should realize by now that the
whole 1.5 million active atari 8-bit users are not going to upgrade to the ST.
When IBM is backing a new comparable machine in the same price range.

Reasons for an upgrade in speed for the
6502, for the atari Xe/Xl machines:

1 Floating Point operations.
Currently the 8-bit rom floating
code is slow.
>>A faster 6502 running around 3.58Mhz
could crank out these calculations
twice as fast.

2 I/O rates.

>>Since the PBI(parallel bus interface)
is driven directly by the cpu, MIO's

and other harddrive interfaces could
be accessed at standard PC speeds.

3 Integer calculations and Data jugling
operations.

>>This is the reason people buys the new
16/32 machines. Everyone wants their
information delivered at a reasonable
speed. Remember for Humans the less
time something requires the more it
seems to be used.

4 The windowing/icon user interface
would be workable in the graphics 8
mode for machines with more than
64K.

The botton line is Any upgrade to the moderately useful XE/XLs line would be
appriciated.

BUT ANY UPGRADES THAT WOULD NOT REACH
A MAJORITY OF THE 8-BIT ATARI COMMUNITY
WOULD NOT TEMPT THE SOFTWARE DEVELOPERS
TO WRITE FOR OUR MACHINES.
MY 8-bit will still be used whether
or not i buy a new computer. Most
of the info-atari8 readers feel the
same way.

Does anyone know the format of .ARC files, as hacked by the ARCX and ARC that were posted a while ago? I've gotten sick of their slowness and low memory requirements, and am contemplating whacking together some new ones. I've looked at dumps of the binaries, but it's not obvious how the files are constructed (not surprising, if they're Huffman encoded). Alternatively, does anyone know how to lay hands on the source for ARCX and ARC? Failing that, does anyone know how to contact the authors? Thanks for any info.

> Failing that, does anyone know how to contact the authors?

I've read articles on the format of .ARC files, but none were in-depth
enough for your purposes. In a nutshell, however, ARC determines
which of four compression techniques to use on each file it's asked to
archive, compresses them, and sticks them together. The 8-bit version
of ARC never uses the 4th technique ("crunching") due to memory
restrictions, but the 8-bit ARCX can unARC files compressed with all
four techniques.
I believe that the 8-bit ARC and ARCX were written in Lightspeed C
by the authors of that language, who frequent the GEnie Atari
Roundtable. I can recall reading a message by one of the authors
explaining that it's pointless to attempt to improve on the speed of
the 8-bit ARC. It's a very calculation-intensive application, and the
Atari is only so fast at these things.
Still, if you're willing to tackle the task in assembler, you may be
able to speed it up a bit...

On another note: I have discovered by much experimentation that ARC
1.2 tends to compress text files such that they contain an extra copy
of their last byte when unARCed. This causes ARCX to generate
checksum errors, which can safely be ignored. Regardless, I find it
safest to ARC things with ARC 1.1 and deARC them with ARCX 1.2.

The 16/32 bit upgrade to the Atari 800 line has been on the dealers shelves
sinse September 1985 !! The problem that most Atari 800 owners have is
one of idenity -- they fail to see what has been placed in front of their
faces.

I of course am talking about the Amiga 1000. I bought my Atari 800 for
its great graphics, sound, and FRIENDLY user interface, BTW its SN is
00232 ! The Amiga 1000 IS the NEXT generation Atari 800 ! The chief
H/W architect for the Atari 2600, Atari 800 and the Amiga 1000 is Jay
Miner ! The Amiga's great MULTITASKING OS is just a super bonus to an
already super computer. BTW my Amiga's SN is D605 - its a preproduction
box !

BTW I have worked for Atari (pre JT), Commodore (during the JT reign), and
Amiga (1984-5). Am I jaded ? YES I will not purchase a JT product ever
again !

I am no longer connected with either Atari or Commodore except that I
own their products.

Amiga 1000 Simply the best computer for 3X the price
Atari 800 Best 8 bit computer built.
Atari 400 Expanded to 48K. Same as above.
C64 Used only to play games on. OS sucks cow sn@t.
VIC20 Same as the C64.
Atari 2600 Great little game machine.

Hans

These comments are mine, mine, mine... however all may share them.

The "world's record" for a 6502 is 24 Mhz (it was a one-of-a-kind
chip). With today's technology (the 6502 is about ten years old)
you could make 32 Mhz versions.

Put that in your '386 and smoke it!

I haven't gotten the 8-bit Extra magazine yet although I did see one briefly at the Summer CES at their booth. If I get one, I'll buy it with the disk. Lately, I have seen a number of problems with programs in ANALOG. I typed in the Fortune Wheel game from last December. I ran into several problems, some I fixed and some I couldn't figure out how to fix. I gave a marked up copy to the girl at their booth in June and she promised to give it to the Editor. I haven't seen any type of corrections in the front where they usually put them. The disk version must have been correct though, because a reader wrote in saying what a wonderful program it was. Personally, I have seen a falling off of the quality in ANALOG.

578. VT52B: Yet Another Terminal Emulator (Part 1 of 3)

Newsgroup: comp.sys.atari.8bit
Date: 1987-09-28 16:29:27 UTC
From: ehs@jumbo.dec.com
Message-ID: <952@jumbo.dec.com>
Source record: 117432

Hardly what the 8-bit Atari world needs most right now, but here's why I often use this one when I just want a Unix terminal (no file transfers):

- It uses the character set I find most legible on my particular monitor (Commodore 1702, composite color). This is a very subjective call, and I make no claims at all about results on a good monochrome monitor.

- It has relatively fast implementations of most escape sequences. These provide the terminal capabilities needed to make the use of a screen-oriented editor (Emacs) bearable.

- The program is small and simple; it loads and initializes quickly.

- Source (in ACTION!) is available for customization and adaptation.

I'm posting VT52B in case anyone else has similar requirements. It is an upgrade of the ACTION! program VT52A posted by Michael Jenkin about a year ago. Michael's font looks bolder and more blocky than the ones used by the other 80 column programs that I've tried. In addition, the proportions of some characters are exaggerated a bit to make the corresponding shapes more distinctive. This is a good trade-off for my eyes and monitor; your mileage may differ. I have modified VT52A by reworking the display management, adding a few new escape sequences, and generally trying to streamline what seemed to be the critical loops. My thanks to Michael for permission to use his character set as well as the general framework of his program.

I am posting the sources for three reasons. First, I don't have a copy of the ACTION! runtime library to link with the object code. Second, this is an edit-and-compile project; there are no runtime menus, and some customization of the source will probably be necessary. Finally, 80-column screen management is done by an "A:" handler that is comparable to the standard "S:" handler. It might be of some interest for other applications, even if you don't care about a terminal emulator.

Most of the revision of VT52A was done as a Sunday afternoon hack, with some further additions and changes suggested by experience with the program. It now does what I need, but there is plenty of room for further development. All my testing has been done with an Atari 800, an Atari 850 interface, and Hayes-incompatible modems at 1200 and 2400 baud.
The mainframes have been VAXen running various versions of Ultrix (essentially similar to BSD 4.2 and 4.3 Unix) with Unipress (Gosling) Emacs as the primary editor. I've had considerable trouble getting other terminal emulators to work in this environment. If you have similar problems getting VT52B to work for you, I'd be interested in hearing about it.

Some documentation and a suggested Unix termcap entry appear in the next message. The message following that contains the ACTION! source code for VT52B.ACT.

579. VT52B: Yet Another Terminal Emulator (Part 2 of 3)

Newsgroup: comp.sys.atari.8bit
Date: 1987-09-28 16:32:37 UTC
From: ehs@jumbo.dec.com
Message-ID: <953@jumbo.dec.com>
Source record: 117433

```
--------------------------------------------------------------------------------

VT52B Documentation

Overview
--------

VT52B consists of two modules. One is a fairly general handler for an
"A:" device that manages a 24 x 80 screen. It provides a
character-oriented output device that recognizes embedded escape
sequences. These escape sequences perform various display control
functions. They support a subset of the VT52 terminal capabilities plus a
few extensions needed for incremental display updates. The other module
is a very simple (perhaps too simple) terminal protocol manager that
attempts to coordinate the K:, R: and A: devices to emulate an
extended VT52 terminal.

The A: handler uses techniques of display list management that are by now
fairly standard and well-known. I hope that most of the code will be
fairly scrutable to an experienced ACTION! programmer. I will not attempt
to explain it here but I will try to answer any specific questions that
arise.

The A: Handler
--------------

The following VT52 escape sequences are supported:

esc-A moves cursor up one line
esc-B moves cursor down one line
esc-C moves cursor right one column
esc-D moves cursor left one column
esc-H homes cursor
esc-I reverse line feed
esc-J clears from cursor to end of screen
esc-K clears from cursor to end of line
esc-Y positions cursor (see VT52 specs for X,Y encoding)

The following extensions are also supported:

esc-F enters 'stand-out' (inverse video) mode
esc-G exits 'stand-out' mode
esc-L inserts blank character space at the cursor
esc-M deletes character at the cursor
esc-N inserts blank line at the cursor
esc-O deletes line containing the cursor
```

A suitable UNIX termcap entry appears at the end of this file. The extension codes have been chosen to be compatible with the "VT-52XL" terminal supported by Chameleon, and the same termcap should be suitable for both.

The support for 'stand-out' mode has not been extensively tested, but it is good enough to do Emacs mode lines and the like. Its use is a mixed blessing, however, since the inverted video can be much less readable. To disable it, remove the next-to-last line from the suggested termcap.

The code could easily be modified to support 'insert' and 'delete' modes directly, and the corresponding incremental updates would be considerably faster. I have not done this because such modality can be disastrous over a noisy or unreliable line.

When the A: device is opened, it allocates space for its display bit maps and custom display lists from the top of available memory as recorded in MEMTOP (location $2E5) and updates MEMTOP. These data structures require approximately 8200 bytes. If sufficient space is not available, the open fails and MEMTOP is not changed.

Terminal Emulation

ASCII characters not on the Atari keyboard can be entered as follows:

{ ctrl-< or shift-<
} ctrl-> or shift->
~ ctrl-backS or shift-backS
` ctrl-.

The emulator does not provide flow control; buffer overruns drop characters. In my experience, this is never a problem at 1200 baud and is not a problem at 2400 for screen-at-a-time output. The program cannot keep up with continuous output at 2400 baud.

The ASCII bell character (^G) produces no visible or audible output.

Installation

You will need an ACTION! cartridge to compile and run this program. You might also have to edit the source to select the options you require, since there is no provision for changing these at runtime. The configuration of the 850 interface (or similar R: interface) is controlled by the following variables, which are declared and initialized at the beginning of the main program module:
speed, wsize, sbits, lf, iparity, oparity
See the 850 manual for tables of possible values and their meanings. Note that the value of 'speed' is 7 less than the tabulated value, e.g.,
speed baud rate
1 300
2 600
3 1200

5 2400
Alternatively, you can modify the calls of XIO_R in the procedure init_R; these variables are not used elsewhere. As it stands, VT52B supports a 1200 baud modem with 8-bit words, 2 stop bits and no parity.

Many monitors will actually display 25 or 26 lines of text. You can take advantage of this by changing the following definitions at the beginning of the module for the A: handler:
NL number of screen lines (normally 24)
NB number of skip lines in top border (normally 3)
LL *must* equal NL-1
DLSize *must* equal NB + 10*NL + 3
I have had good results with NL=25 and NB=2. If you change NL, be sure to change your termcap entry to agree.

I experimented with several background colors for the display. I eventually settled on a pale blue that seemed to be the best compromise between contrast and flicker on my particular monitor. See the procedure init_A if you want to change this.

The emulator module contains a procedure load_R. This is a machine-code insert essentially similar to the code in the autorun file that downloads the R: handlers from the 850. I added it when I was having some trouble with 850 (re)initialization. I left it in because it makes the object file somewhat smaller and easier to build. If you have a different interface unit or prefer a different handler, delete init_R and prepend your handler to the object file in the usual way.

You must compile this program with lower case enabled. You must also compile it with space for the R: handlers reserved in low memory. The simplest way to do this is to load the handler you intend to use (by executing the AUTORUN.SYS file, for example) before compiling VT52B.ACT. You can then execute the compiled program directly or save it for later execution using the DOS "L" command or equivalent. If you deleted init_R, you must prepend an appropriate R: handler. Alternatively, you can set the code origin to reserve space for your handler as described on page 144 of the ACTION! manual. You are in terminal emulation mode as soon as execution begins.

Note: At least some versions of the 850 will not download the R: handlers a second time until the power has been cycled on either the console computer or the 850. Thus if you load the handlers (e.g., with the standard AUTORUN.SYS file), do something that destroys them (e.g., going to DOS without a MEM.SAV file) and then attempt to reload them, you will be left without warning with bad handlers.

Suggested Termcap Entry

Here's one that has worked for me:

:am:pt:tc=vt52:
a2|atari+|vt52xl|atari vt52+ emulator:\
:al=\EN:dl=\EO:im=:ei=:ic=\EL:dm=:ed=:dc=\EM:\
:so=\EF:se=\EG:\
:tc=atari:
```

Note that it can take some extra work to get your favorite program to notice changes in the terminal type and capabilities. If the program is able to use the escape sequences, you should notice a definite difference between vt52 and atari+ termcap entries. Here's a script from our system administrator that works for Emacs:

```
#! /bin/csh -f
#
# vt52b-mode - setup terminal for vt52b mode.
#
stty dec new cr0
set noglob
setenv TERMCAP atari.termcap
setenv TERM atari+
eval `tset -s -I -Q`
set term = atari+
unset noglob
```

Replace "atari.termcap" with the name of the file containing a termcap entry similar to the one above.

A long time ago I said I'd port ARC in Action!, but I never finished,
and my 800XL has since bit the dust. However, I have full docs and source
code in C if you want them. I'm currently porting ARC 5.20 to my ST.
A description of the ARC header follows....
-=-

ARC-FILE.INF, created by Keith Petersen, W8SDZ, 21-Sep-86, extracted
from UNARC.INF by Robert A. Freed.

From: Robert A. Freed
Subject: Technical Information for ARC files
Date: June 24, 1986

Note: In the following discussion, UNARC refers to my CP/M-80 program
for extracting files from MSDOS ARCs. The definitions of the ARC file
format are based on MSDOS ARC512.EXE.

ARCHIVE FILE FORMAT

Component files are stored sequentially within an archive. Each entry
is preceded by a 29-byte header, which contains the directory
information. There is no wasted space between entries. (This is in
contrast to the centralized directory used by Novosielski libraries.
Although random access to subfiles within an archive can be noticeably
slower than with libraries, archives do have the advantage of not
requiring pre-allocation of directory space.)

Archive entries are normally maintained in sorted name order. The
format of the 29-byte archive header is as follows:

Byte 1: 1A Hex.
This marks the start of an archive header. If this byte is not found
when expected, UNARC will scan forward in the file (up to 64K bytes)
in an attempt to find it (followed by a valid compression version).
If a valid header is found in this manner, a warning message is
issued and archive file processing continues. Otherwise, the file is
assumed to be an invalid archive and processing is aborted. (This is
compatible with MS-DOS ARC version 5.12). Note that a special
exception is made at the beginning of an archive file, to accomodate
"self-unpacking" archives (see below).

Byte 2: Compression version, as follows:

0 = end of file marker (remaining bytes not present)
1 = unpacked (obsolete)
2 = unpacked

3 = packed
4 = squeezed (after packing)
5 = crunched (obsolete)
6 = crunched (after packing) (obsolete)
7 = crunched (after packing, using faster hash algorithm) (obsolete)
8 = crunched (after packing, using dynamic LZW variations)

Bytes 3-15: ASCII file name, nul-terminated.

(All of the following numeric values are stored low-byte first.)

Bytes 16-19: Compressed file size in bytes.

Bytes 20-21: File date, in 16-bit MS-DOS format:
Bits 15:9 = year - 1980
Bits 8:5 = month of year
Bits 4:0 = day of month
(All zero means no date.)

Bytes 22-23: File time, in 16-bit MS-DOS format:
Bits 15:11 = hour (24-hour clock)
Bits 10:5 = minute
Bits 4:0 = second/2 (not displayed by UNARC)

Bytes 24-25: Cyclic redundancy check (CRC) value (see below).

Bytes 26-29: Original (uncompressed) file length in bytes.
(This field is not present for version 1 entries, byte 2 = 1.
I.e., in this case the header is only 25 bytes long. Because
version 1 files are uncompressed, the value normally found in
this field may be obtained from bytes 16-19.)

SELF-UNPACKING ARCHIVES

A "self-unpacking" archive is one which can be renamed to a .COM file
and executed as a program. An example of such a file is the MS-DOS
program ARC512.COM, which is a standard archive file preceded by a
three-byte jump instruction. The first entry in this file is a simple
"bootstrap" program in uncompressed form, which loads the subfile
ARC.EXE (also uncompressed) into memory and passes control to it. In
anticipation of a similar scheme for future distribution of UNARC, the
program permits up to three bytes to precede the first header in an
archive file (with no error message).

CRC COMPUTATION

Archive files use a 16-bit cyclic redundancy check (CRC) for error
control. The particular CRC polynomial used is x^16 + x^15 + x^2 + 1,
which is commonly known as "CRC-16" and is used in many data
transmission protocols (e.g. DEC DDCMP and IBM BSC), as well as by
most floppy disk controllers. Note that this differs from the CCITT
polynomial (x^16 + x^12 + x^5 + 1), which is used by the XMODEM-CRC

protocol and the public domain CHEK program (although these do not adhere strictly to the CCITT standard). The MS-DOS ARC program does perform a mathematically sound and accurate CRC calculation. (We mention this because it contrasts with some unfortunately popular public domain programs we have witnessed, which from time immemorial have based their calculation on an obscure magazine article which contained a typographical error!)

Additional note (while we are on the subject of CRC's): The validity of using a 16-bit CRC for checking an entire file is somewhat questionable. Many people quote the statistics related to these functions (e.g. "all two-bit errors, all single burst errors of 16 or fewer bits, 99.997% of all single 17-bit burst errors, etc."), without realizing that these claims are valid only if the total number of bits checked is less than 32767 (which is why they are used in small-packet data transmission protocols). I.e., for file sizes in excess of about 4K bytes, a 16-bit CRC is not really as good as what is often claimed. This is not to say that it is bad, but there are more reliable methods available (e.g. the 32-bit AUTODIN-II polynomial). (End of lecture!)

> Does anyone know the format of .ARC files, as hacked by the ARCX and ARC
> that were posted a while ago?
> Failing that, does anyone know how to contact the authors?

I've read articles on the format of .ARC files, but none were in-depth
enough for your purposes. In a nutshell, however, ARC determines
which of four compression techniques to use on each file it's asked to
archive, compresses them, and sticks them together. The 8-bit version
of ARC never uses the 4th technique ("crunching") due to memory
```

restrictions, but the 8-bit ARCX can unARC files compressed with all
four techniques.
I believe that the 8-bit ARC and ARCX were written in Lightspeed C
by the authors of that language, who frequent the GEnie Atari
Roundtable. I can recall reading a message by one of the authors
explaining that it's pointless to attempt to improve on the speed of
the 8-bit ARC. It's a very calculation-intensive application, and the
Atari is only so fast at these things.
Still, if you're willing to tackle the task in assembler, you may be
able to speed it up a bit...

On another note: I have discovered by much experimentation that ARC
1.2 tends to compress text files such that they contain an extra copy
of their last byte when unARCed. This causes ARCX to generate
checksum errors, which can safely be ignored. Regardless, I find it
safest to ARC things with ARC 1.1 and deARC them with ARCX 1.2.

Subject: VT52B: Yet Another Terminal Emulator (Part 2 of 3)
To: info-atari8@score.stanford.edu

VT52B Documentation

Overview

VT52B consists of two modules. One is a fairly general handler for an
"A:" device that manages a 24 x 80 screen. It provides a
character-oriented output device that recognizes embedded escape
sequences. These escape sequences perform various display control
functions. They support a subset of the VT52 terminal capabilities plus a
few extensions needed for incremental display updates. The other module
is a very simple (perhaps too simple) terminal protocol manager that
attempts to coordinate the K:, R: and A: devices to emulate an
extended VT52 terminal.

The A: handler uses techniques of display list management that are by now
fairly standard and well-known. I hope that most of the code will be
fairly scrutable to an experienced ACTION! programmer. I will not attempt
to explain it here but I will try to answer any specific questions that
arise.

The A: Handler

The following VT52 escape sequences are supported:

esc-A moves cursor up one line
esc-B moves cursor down one line
esc-C moves cursor right one column
esc-D moves cursor left one column
esc-H homes cursor
esc-I reverse line feed
esc-J clears from cursor to end of screen
esc-K clears from cursor to end of line
esc-Y positions cursor (see VT52 specs for X,Y encoding)

The following extensions are also supported:

esc-F enters 'stand-out' (inverse video) mode
esc-G exits 'stand-out' mode
esc-L inserts blank character space at the cursor
esc-M deletes character at the cursor
esc-N inserts blank line at the cursor
esc-O deletes line containing the cursor

A suitable UNIX termcap entry appears at the end of this file. The extension codes have been chosen to be compatible with the "VT-52XL" terminal supported by Chameleon, and the same termcap should be suitable for both.

The support for 'stand-out' mode has not been extensively tested, but it is good enough to do Emacs mode lines and the like. Its use is a mixed blessing, however, since the inverted video can be much less readable. To disable it, remove the next-to-last line from the suggested termcap.

The code could easily be modified to support 'insert' and 'delete' modes directly, and the corresponding incremental updates would be considerably faster. I have not done this because such modality can be disastrous over a noisy or unreliable line.

When the A: device is opened, it allocates space for its display bit maps and custom display lists from the top of available memory as recorded in MEMTOP (location $2E5) and updates MEMTOP. These data structures require approximately 8200 bytes. If sufficient space is not available, the open fails and MEMTOP is not changed.

Terminal Emulation

ASCII characters not on the Atari keyboard can be entered as follows:

{ ctrl-< or shift-<
} ctrl-> or shift->
~ ctrl-backS or shift-backS
` ctrl-.

The emulator does not provide flow control; buffer overruns drop characters. In my experience, this is never a problem at 1200 baud and is not a problem at 2400 for screen-at-a-time output. The program cannot keep up with continuous output at 2400 baud.

The ASCII bell character (^G) produces no visible or audible output.

Installation

You will need an ACTION! cartridge to compile and run this program. You might also have to edit the source to select the options you require, since there is no provision for changing these at runtime. The configuration of the 850 interface (or similar R: interface) is controlled by the following variables, which are declared and initialized at the beginning of the main program module:
speed, wsize, sbits, lf, iparity, oparity
See the 850 manual for tables of possible values and their meanings. Note that the value of 'speed' is 7 less than the tabulated value, e.g.,
speed baud rate
1 300
2 600
3 1200
5 2400
Alternatively, you can modify the calls of XIO_R in the procedure init_R; these variables are not used elsewhere. As it stands, VT52B supports a 1200 baud modem with 8-bit words, 2 stop bits and no parity.

Many monitors will actually display 25 or 26 lines of text. You can take advantage of this by changing the following definitions at the beginning of the module for the A: handler:
NL number of screen lines (normally 24)
NB number of skip lines in top border (normally 3)
LL *must* equal NL-1
DLSize *must* equal NB + 10*NL + 3
I have had good results with NL=25 and NB=2. If you change NL, be sure to change your termcap entry to agree.

I experimented with several background colors for the display. I eventually settled on a pale blue that seemed to be the best compromise between contrast and flicker on my particular monitor. See the procedure init_A if you want to change this.

The emulator module contains a procedure load_R. This is a machine-code insert essentially similar to the code in the autorun file that downloads the R: handlers from the 850. I added it when I was having some trouble with 850 (re)initialization. I left it in because it makes the object file somewhat smaller and easier to build. If you have a different interface unit or prefer a different handler, delete init_R and prepend your handler to the object file in the usual way.

You must compile this program with lower case enabled. You must also compile it with space for the R: handlers reserved in low memory. The

simplest way to do this is to load the handler you intend to use (by executing the AUTORUN.SYS file, for example) before compiling VT52B.ACT. You can then execute the compiled program directly or save it for later execution using the DOS "L" command or equivalent. If you deleted init_R, you must prepend an appropriate R: handler. Alternatively, you can set the code origin to reserve space for your handler as described on page 144 of the ACTION! manual. You are in terminal emulation mode as soon as execution begins.

Note: At least some versions of the 850 will not download the R: handlers a second time until the power has been cycled on either the console computer or the 850. Thus if you load the handlers (e.g., with the standard AUTORUN.SYS file), do something that destroys them (e.g., going to DOS without a MEM.SAV file) and then attempt to reload them, you will be left without warning with bad handlers.

Suggested Termcap Entry

Here's one that has worked for me:

```
dw|vt52|decvt52:\
:cr=^M:do=^J:nl=^J:bl=^G:le=^H:bs:cd=\EJ:ce=\EK:\
:cl=\EH\EJ:cm=\EY%+ %+ :co#80:li#24:nd=\EC:ta=^I:pt:sr=\EI:\
:up=\EA:ku=\EA:kd=\EB:kr=\EC:kl=\ED:kb=^H:
a1|atari|atari vt52 emulator:\
:am:pt:tc=vt52:
a2|atari+|vt52xl|atari vt52+ emulator:\
:al=\EN:dl=\EO:im=:ei=:ic=\EL:dm=:ed=:dc=\EM:\
:so=\EF:se=\EG:\
:tc=atari:
```

Note that it can take some extra work to get your favorite program to notice changes in the terminal type and capabilities. If the program is able to use the escape sequences, you should notice a definite difference between vt52 and atari+ termcap entries. Here's a script from our system administrator that works for Emacs:

```
#! /bin/csh -f
#
# vt52b-mode - setup terminal for vt52b mode.
#
stty dec new cr0
set noglob
setenv TERMCAP atari.termcap
setenv TERM atari+
eval `tset -s -I -Q`
set term = atari+
unset noglob
```

Replace "atari.termcap" with the name of the file containing a termcap entry similar to the one above.

From: jumbo!ehs@decwrl.dec.com (Ed Satterthwaite)
Subject: VT52B: Yet Another Terminal Emulator (Part 1 of 3)
To: info-atari8@score.stanford.edu

Hardly what the 8-bit Atari world needs most right now, but here's why I often use this one when I just want a Unix terminal (no file transfers):

- It uses the character set I find most legible on my particular monitor (Commodore 1702, composite color). This is a very subjective call, and I make no claims at all about results on a good monochrome monitor.

- It has relatively fast implementations of most escape sequences. These provide the terminal capabilities needed to make the use of a screen-oriented editor (Emacs) bearable.

- The program is small and simple; it loads and initializes quickly.

- Source (in ACTION!) is available for customization and adaptation.

I'm posting VT52B in case anyone else has similar requirements. It is an upgrade of the ACTION! program VT52A posted by Michael Jenkin about a year ago. Michael's font looks bolder and more blocky than the ones used by the other 80 column programs that I've tried. In addition, the proportions of some characters are exaggerated a bit to make the corresponding shapes more distinctive. This is a good trade-off for my eyes and monitor; your mileage may differ. I have modified VT52A by reworking the display management, adding a few new escape sequences, and generally trying to streamline what seemed to be the critical loops. My thanks to Michael for permission to use his character set as well as the general framework of his program.

I am posting the sources for three reasons. First, I don't have a copy of the ACTION! runtime library to link with the object code. Second, this is an edit-and-compile project; there are no runtime menus, and some customization of the source will probably be necessary. Finally, 80-column screen management is done by an "A:" handler that is comparable to the standard "S:" handler. It might be of some interest for other applications, even if you don't care about a terminal emulator.

Most of the revision of VT52A was done as a Sunday afternoon hack, with some further additions and changes suggested by experience with the program. It now does what I need, but there is plenty of room for further development. All my testing has been done with an Atari 800, an Atari 850 interface, and Hayes-incompatible modems at 1200 and 2400 baud.
The mainframes have been VAXen running various versions of Ultrix

(essentially similar to BSD 4.2 and 4.3 Unix) with Unipress (Gosling)
Emacs as the primary editor. I've had considerable trouble getting other
terminal emulators to work in this environment. If you have similar
problems getting VT52B to work for you, I'd be interested in hearing about
it.

Some documentation and a suggested Unix termcap entry appear in the next
message. The message following that contains the ACTION! source code for
VT52B.ACT.

The 16/32 bit upgrade to the Atari 800 line has been on the dealers shelves
sinse September 1985 !! The problem that most Atari 800 owners have is
one of idenity -- they fail to see what has been placed in front of their
faces.

I of course am talking about the Amiga 1000. I bought my Atari 800 for
its great graphics, sound, and FRIENDLY user interface, BTW its SN is
00232 ! The Amiga 1000 IS the NEXT generation Atari 800 ! The chief
H/W architect for the Atari 2600, Atari 800 and the Amiga 1000 is Jay
Miner ! The Amiga's great MULTITASKING OS is just a super bonus to an
already super computer. BTW my Amiga's SN is D605 - its a preproduction
box !

BTW I have worked for Atari (pre JT), Commodore (during the JT reign), and
Amiga (1984-5). Am I jaded ? YES I will not purchase a JT product ever

again !

I am no longer connected with either Atari or Commodore except that I
own their products.

Amiga 1000 Simply the best computer for 3X the price
Atari 800 Best 8 bit computer built.
Atari 400 Expanded to 48K. Same as above.
C64 Used only to play games on. OS sucks cow sn@t.
VIC20 Same as the C64.
Atari 2600 Great little game machine.

Hans

These comments are mine, mine, mine... however all may share them.

I might nte, for those of you who were looking for a trackball, that Kaybee
Toys, an apaprently nationwide chain, is selling Atari trackballs for
$8. Also radio controlled joysticks, a pair for $12, but those just
seem so decadent...

Disclaimer: I have no relationship with Kaybee Toys except as a customer.
(I buy all my bubble-soap there.)

From time to time I am reminded by a message asking the operation
of the lists that it is necessary to periodically send out the
welcome message. It contains valuable information about the location
of information.

I would appreciate receiving updates to this information (sent to
abrams@mitre.arpa) and offers to help fix whatever is broken. At
present I have some doubts about certain items; I hope I am wrong.

Marshall Abrams

1. Welcome

- -------
```

Welcome to info-atari.

2. Sending Messages

- ------- --------

You may send messages to all "subscribers" by address-
ing it to
info-atari8@score.stanford.edu
and/or
info-atari16@score.stanford.edu

Administrative messages should be sent to
info-atari{8,16}-request.

Please do NOT send general messages to this address. Your
moderators get enough mail as it is!

3. Ground Rules

- ------ -----

All messages should be in good taste. Commercial mes-
sages and advertisements are not permitted. When answering a
question, please consider carefully whether the answer
should go to the whole list, or just to the person who asked
the question.

The following ground rules should make the use of this
(or of any other) mailing list much easier:

* never send a message that a totally irrelevant to
the mailing list's purpose to a mailing list. This
especially includes any expressions of irritation at
another list member.

* never forward a message that is totally irrelevant
to the mailing list's purpose to a mailing list.

* when replying to a message on a mailing list, reply
only to the sender of the message unless the reply
is of interest to the entire mailing list.

* avoid inserting the message being replied to in a
reply, especially in a message going to a mailing
list. The context of the reply should be clear from
your reply and from various mailer functionalities
such as Message-ID.

* when replying to an earlier reply that violates the
previous rule, ABSOLUTELY DO NOT make matters worse
by adding your own violation.

4. LISTSERV

- --------

LISTSERV provides a number of features which you can
access by sending mail (note) to LISTSERV. Only the barest

minimum are described herein. On Bitnet messages should be sent to your nearest LISTSERV (the one from which you receive the info-atari digests). (If your address is not on Bitnet, an address for file servers is given below.) All mail sent to LISTSERV contains command lines. LISTSERV will respond by return mail. No subject is necessary in such mail. For more information send the command
INFO

4.1. List Names

The list_name for 16-bit Ataris is INFO-A16. The list_name for 8-bit Ataris is INFO-A8. These list names are used by Bitnet addressees for subscribing and unsubscribing and by everyone for obtaining back copies of news digests. The list_names for programs stored in the archives are PROG-A16 and PROG-A8.

4.2. (Un)Subscribing

If you are on Bitnet you may add or remove yourself from the distribution list. It would greatly convenience the moderators if you would do so when you no longer wish to receive digests.

The command to join the list is
SUBSCRIBE list_name User_name

The command to remove yourself from the list is
UNSUBSCRIBE list_name

Note that the list was established with all user_names unknown. To enter your name, send a SUBSCRIBE command.

It would be most convenient if users took care of their own subscribing and unsubscribing, but messages to INFO-ATARI-REQUEST{8,16}@SCORE.STANFORD.EDU will still be accepted.

4.3. File Server (Archives)

The following service is being installed beginning February 1987; we will announce when everything is in place and "known" to be working.

All messages are in the archives. In addition, some contributed programs are also there. You can obtain copies of files from LISTSERV by sending a message in the specified format.

If you are on ARPAnet (or gatewayed to it), your mail
should be addressed to
LISTSERV%CANADA01.BITNET@WISCVM.WISC.EDU

To obtain a list of files in the file server, the com-
mand is
INDEX list_name

The command to obtain a specific file is
GET list_name file_name

for example,
GET INFO-A16 87-00076

If you want to learn more, send the message
HELP

only to the sender of the message unless the reply
is of interest to the entire mailing list.

* avoid inserting the message being replied to in a
reply, especially in a message going to a mailing
list. The context of the reply should be clear from
your reply and from various mailer functionalities
such as Message-ID.

* when replying to an earlier reply that violates the
previous rule, ABSOLUTELY DO NOT make matters worse
by adding your own violation.

4. Archives

- --------

Archives are kept in several places in formats avail-
able to everyone. As described below, if you are on
ARPANET/DDN you will probably find it more convenient to
retrieve files from the archive on radc-softvax.arpa using
FTP. If you are not on ARPANET/DDN, or are unable to use
FTP, you will be able to retrieve files from archives dis-
tributed over several Bitnet hosts by sending mail (notes)
to a program called LISTSERV.

4.1. Archives on radc-softvax.arpa

- - -------- -- ---- ------- ----

Files from radc-softvax.arpa are available by FTP. FTP
will work only for hosts directly connected to ARPANET/DDN.
Please obtain local documentation and advice for the FTP
user programming running on your host. There are two direc-
tories under the anonymous account. One for atari8 and one
for atari16.

FTP to radc-softvax using login:guest and
password:guest. To get the current list of available atari16
files do a 'get atari16/files.doc'. All of the atari16 files
are stored in the atari16 subdirectory. If you need any
other information, contact Marc Poulin.

The archive is maintained by Rodney Peck (Peck@radc-
multics.arpa) and Marc Poulin (Poulin@radc-multics.arpa or
Archives@radc-softvax.arpa).

4.2. LISTSERV

LISTSERV provides access to files for everyone who can send mail, independent of their location. Note, however, that intermediate notes have been known to refuse to handle long messages or have damaged them in transit. LISTSERV provides a number of features which you can access by sending mail (note) to LISTSERV. Only the barest minimum are described herein. On Bitnet messages should be sent to your nearest LISTSERV (the one from which you receive the info-atari digests). (If your address is not on Bitnet, an address for file servers is given below.) All mail sent to LISTSERV contains command lines. LISTSERV will respond by return mail. No subject is necessary in such mail. For more information send the command
INFO

4.2.1. List Names

The list_name for 16-bit Ataris is INFO-A16. The list_name for 8-bit Ataris is INFO-A8. These list names are used by Bitnet addressees for subscribing and unsubscribing and by everyone for obtaining back copies of news digests. The list_names for programs stored in the archives are PROG-A16 and PROG-A8.

4.2.2. (Un)Subscribing

If you are on Bitnet you may add or remove yourself from the distribution list. It would greatly convenience the moderators if you would do so when you no longer wish to receive digests.

The command to join the list is
SUBSCRIBE list_name User_name

The command to remove yourself from the list is
UNSUBSCRIBE list_name

It would be most convenient if users took care of their own subscribing and unsubscribing, but messages to INFO-ATARI-REQUEST{8,16}@SCORE.STANFORD.EDU will still be accepted.

4.2.3. Accessing Program & Digest Archives

All digests are in the archives. There is a separate program library. You can obtain copies of files from LISTSERV by sending a message in the specified format.

If you are on ARPAnet (or gatewayed to it), your mail concernin 16-bit Atari information should be addressed to
LISTSERV%CANADA01.BITNET@WISCVM.WISC.EDU

Mail concernin 8-bit Atari information should be addressed to
LISTSERV%TCSVM.BITNET@WISCVM.WISC.EDU

To obtain a list of files in the file server, the command is
INDEX list_name

The command to obtain a specific file is
GET list_name file_name

for example,
GET INFO-A16 87-00076

If you want to learn more, send the message
HELP

4.2.4. LISTSERV Moderators

The person to contact if you are having problems (un)subscribing is Harry Williams (harry@marist.bitnet). The moderator of the 16-bit digest archives is Peter Jasper-Fayer (sofpjf@uoguelph.bitnet). The moderator of the 16-bit program archives is Richard Werezak (carson@mcmaster.bitnet). The moderator of the 8-bit archives is John Voigt (sysbjav@tcsvm.bitnet). The moderator of the 8-bit program archives is Arnold de Leon (adeleon@hmcvax.bitnet).

4.2.5. Information Concerning 16-bit Archive Organization

The digests are numbered sequentially as they come in. Sometimes the files arrive here out of order, or with missing ones, or with extra ones or with mail from BITNET users requesting information. Often the moderator has to logon to LISTSERV and re-name the files according to the "Subject:" line within it. Those "Subject:" lines are what end up in the indexes (in both "-A16" lists)

The program files are largely extracts from the digests (INFO-A16). As far as possible, they are numbered the same as the digests they came from. Other programs were inserted somewhere in the list. The numbers of these "inserted" files were selected so that they would appear in the index at about the correct CHRONOLOGICAL sequence. If no programs were included in the digests, and nocontributions were received, then those spaces in the index numbers were left blank.

Subject: Re: ARC file format?
To: info-atari8@score.stanford.edu

A long time ago I said I'd port ARC in Action!, but I never finished,
and my 800XL has since bit the dust. However, I have full docs and source
code in C if you want them. I'm currently porting ARC 5.20 to my ST.
A description of the ARC header follows....
-=-

ARC-FILE.INF, created by Keith Petersen, W8SDZ, 21-Sep-86, extracted
from UNARC.INF by Robert A. Freed.

From: Robert A. Freed
Subject: Technical Information for ARC files
Date: June 24, 1986

Note: In the following discussion, UNARC refers to my CP/M-80 program
for extracting files from MSDOS ARCs. The definitions of the ARC file
format are based on MSDOS ARC512.EXE.

ARCHIVE FILE FORMAT

Component files are stored sequentially within an archive. Each entry
is preceded by a 29-byte header, which contains the directory
information. There is no wasted space between entries. (This is in
contrast to the centralized directory used by Novosielski libraries.
Although random access to subfiles within an archive can be noticeably
slower than with libraries, archives do have the advantage of not
requiring pre-allocation of directory space.)

Archive entries are normally maintained in sorted name order. The
format of the 29-byte archive header is as follows:

Byte 1: 1A Hex.
This marks the start of an archive header. If this byte is not found
when expected, UNARC will scan forward in the file (up to 64K bytes)
in an attempt to find it (followed by a valid compression version).
If a valid header is found in this manner, a warning message is
issued and archive file processing continues. Otherwise, the file is
assumed to be an invalid archive and processing is aborted. (This is
compatible with MS-DOS ARC version 5.12). Note that a special
exception is made at the beginning of an archive file, to accomodate
"self-unpacking" archives (see below).

Byte 2: Compression version, as follows:

0 = end of file marker (remaining bytes not present)
1 = unpacked (obsolete)
2 = unpacked
3 = packed

4 = squeezed (after packing)
5 = crunched (obsolete)
6 = crunched (after packing) (obsolete)
7 = crunched (after packing, using faster hash algorithm) (obsolete)
8 = crunched (after packing, using dynamic LZW variations)

Bytes 3-15: ASCII file name, nul-terminated.

(All of the following numeric values are stored low-byte first.)

Bytes 16-19: Compressed file size in bytes.

Bytes 20-21: File date, in 16-bit MS-DOS format:
Bits 15:9 = year - 1980
Bits 8:5 = month of year
Bits 4:0 = day of month
(All zero means no date.)

Bytes 22-23: File time, in 16-bit MS-DOS format:
Bits 15:11 = hour (24-hour clock)
Bits 10:5 = minute
Bits 4:0 = second/2 (not displayed by UNARC)

Bytes 24-25: Cyclic redundancy check (CRC) value (see below).

Bytes 26-29: Original (uncompressed) file length in bytes.
(This field is not present for version 1 entries, byte 2 = 1.
I.e., in this case the header is only 25 bytes long. Because
version 1 files are uncompressed, the value normally found in
this field may be obtained from bytes 16-19.)

SELF-UNPACKING ARCHIVES

A "self-unpacking" archive is one which can be renamed to a .COM file
and executed as a program. An example of such a file is the MS-DOS
program ARC512.COM, which is a standard archive file preceded by a
three-byte jump instruction. The first entry in this file is a simple
"bootstrap" program in uncompressed form, which loads the subfile
ARC.EXE (also uncompressed) into memory and passes control to it. In
anticipation of a similar scheme for future distribution of UNARC, the
program permits up to three bytes to precede the first header in an
archive file (with no error message).

CRC COMPUTATION

Archive files use a 16-bit cyclic redundancy check (CRC) for error
control. The particular CRC polynomial used is x^16 + x^15 + x^2 + 1,
which is commonly known as "CRC-16" and is used in many data
transmission protocols (e.g. DEC DDCMP and IBM BSC), as well as by
most floppy disk controllers. Note that this differs from the CCITT
polynomial (x^16 + x^12 + x^5 + 1), which is used by the XMODEM-CRC
protocol and the public domain CHEK program (although these do not

adhere strictly to the CCITT standard). The MS-DOS ARC program does perform a mathematically sound and accurate CRC calculation. (We mention this because it contrasts with some unfortunately popular public domain programs we have witnessed, which from time immemorial have based their calculation on an obscure magazine article which contained a typographical error!)

Additional note (while we are on the subject of CRC's): The validity of using a 16-bit CRC for checking an entire file is somewhat questionable. Many people quote the statistics related to these functions (e.g. "all two-bit errors, all single burst errors of 16 or fewer bits, 99.997% of all single 17-bit burst errors, etc."), without realizing that these claims are valid only if the total number of bits checked is less than 32767 (which is why they are used in small-packet data transmission protocols). I.e., for file sizes in excess of about 4K bytes, a 16-bit CRC is not really as good as what is often claimed. This is not to say that it is bad, but there are more reliable methods available (e.g. the 32-bit AUTODIN-II polynomial). (End of lecture!)

586. Critcism or Embarassment,ATARI corp?

Newsgroup: comp.sys.atari.8bit
Date: 1987-10-01 20:23:00 UTC
From: DFLINT02@ULKYVX.BITNET
Message-ID: <8710012029.AA22072@ucbvax.Berkeley.EDU>
Source record: 117440

Tramiel and many members of his staff have considered the 8-bit machine, enhanced, as a competitor for the ST. Also the Game machine image of the ATARI 8-bits machines does not seem to warrant any type of upgrade. I have stated that i would support any upgrades that ATARI would develope for the 8-bit. Besides a little criticism never hurts. Tramiel does not take the 8-bit to seriously. JWT and Landon Dyer are the most helpful people atari has on this net.

Answer this question why did a ATARI try to block the release of the PD 8-bit emulator for the ST????? Don't quote Propietary OS.

587. New Atari Hardware News

Newsgroup: comp.sys.atari.8bit
Date: 1987-10-02 09:22:04 UTC
From: conklin@eecae.UUCP
Message-ID: <3074@eecae.UUCP>
Source record: 117441

The following is a collection of hardware announcements that I have collected as a function of being the Admin for the Club Network. I always try and keep the Club's 8-bit people abreat of the latest news, so, while commercial in nature, this isn't meant as an ad proper as much as a list of new hardware and software that I have found for the 8-bit.

From Terrific Corp. I have received the following information about this home control system:
"The X-10 POWERMANAGER SYSTEM

Now you can finally use your Atari Home Computer to conveniently create, store and recall programs that can be loaded into the X-10 PowerHouse controller to control lights, appliances and other devices hooked up to X-10 control modules throughout your home.

There are two X-10 interface kits available from Terrific Corp. One kit includes an X--10 PowerHouse Computer interface, a special Atari interface adaptor and the Powermanager software. For those who already have the PowerHouse computer interface, the software and adaptor are available seperately.

The Powermanager software takes full advantage of the PowerHous interface. Features include:

-Up to 256 modules can be individually controlled. Modules can be grouped together to allow control of an 'infinite' number of devices.
-Lights and appliances can be programmed to turn on or off at specified times through the use of a timer event schedule. In addition, lights can be programmed to dim to 16 intenstities.
-Timer event schedules can hold up to 128 events, a single event can control up to 16 modules.
-Timer event schedules can be created, stored and edited on disk.
-Modules can be controlled instantly from the Atari.
-Software allows use of joystick or keyboard
-48K required, machine language, drive.

Terrific Corp.
17 St Mary's Court
Brooklin, MA 02146
(617) 232-2317"

You all know these things. The dreaded BSR controller returns. Actually, these really ARE cool. I have a friend with equivalent software on his TRS Coco. It's all very impressive and neat. The only problem is that control modules get expensive as you

wire up a whole house. He bought out an RS inventory at $3 a
module or so. The only way to do it.

More exciting Atari 8bit hardware came recently from the yet scarier
IRATA VERLAG corp. Their offerings included:

512K card for the 800XL....$170
512K special chip for use
with above card.....$52
Card and Chip together.....$200
6 OS System Box : Basically the equivalent of the RAM-ROD XL.
This allows you to have 6 diffeent OS chips and then to
select amongst them with a switch.
.....$50
HIGH CHIP: for people who have the Happy drive enhancement.
This chip has a hidden menu. Hold don select while you press
RESET and you get a menu with the options for COLD START,
SECTOR COPY, or TURN HAPPY ON/OFF. "Saves times."
.....$50
XE CHIP WITH RAMDISK.....$75 (doesn't say anything else!)
OLD SYS CHIP:
Replacement OS chip for XL/XE's for 400/800 compatibility
.....$???

All chips that have something to do with the Happy have a special
feature. For people who know machine language, the happy
can load any protected disk into the happy memory, then
turn around and write the binary data back onto a normal
formatted diskette. This allows you to then take a sector
editor to look at the actual bit stream from the original
disk to learn how it is set up.

Some new 8bit software:
100 New Print Shop pictures....$7
The Editor.....$15
The Super Label II.....$15

THE XL/XE SUPER TURBO INTERFACE:
This is a disk interface for the Atari 8bit that allows you
to do many different things. They are:
-Use IBM 5.25" and ST 3.5" disk drives for fast seek and large
storage capacities
-Back up ANY protected 8bit software
-Transfer between any of the three (Atari, IBM, 3. 5") formats.
-Backs up all protected ST & IBM software too!?
-Has built in 8bit pritnter interface
-For people with Happy drives, the SUPER TURBO works with the
Happy and kicks the baud rate to an awesome.....
(drum roll) * 150,000 * baud. It loads programs in 7 seconds
and does whole disk copies in 27 seconds. (THIS, I gotta see.)

SUPER TURBO INTERFACE.....$250

I am NOT affiliated with these people in any way. In fact,
I have absolutely no idea where they are or came from. I just
get a lot of release info in the process of searching out
what's new for Club Net 8bit owners and thought it might
interest some of the netters. The english on the IRATA
ad left something to be desired, so be sure and give these
guys the third degree when you call to make sure it is
ligit. Forgot to list their address/phone number. It's

IRATA VERLAG
1272B POTTER DRIVE
COLO SPRINGS, CO 80909
(303) 596-0135

I also talked to ICD today and they claimed that the SPARTADOS-X
cart would be available for Xmas.

Such is excitement. No news from the we fine brave souls in
the Turbo-project. We just got the 65802. Hope!

Terry Conklin
ihnp4!msudoc!conklin
Club Lansing (517) 372-3131 (gets all this junk first.)
Club II (313) 334-8877 (next day or so)
Club III (714) xxx-xxxx (at this rate, we may never know)
So this is what happens when BBS's go Imperialist. It becomes
some sort of public entity. Swell. Does that mean I have to
housebreak it?

588. Standalone OmniCom

Newsgroup: comp.sys.atari.8bit
Date: 1987-10-02 21:55:16 UTC
From: jhs@MITRE-BEDFORD.ARPA.UUCP
Message-ID: <8710022155.AA22666@mitre-bedford.ARPA>
Source record: 117442

A couple of weeks ago, I posted a new "shareware" version of CDY's OmniCom to the net. Unlike the original OmniCom, this version does not require the installation of the OMNIVIEW chip. I have the feeling it made it out to BITNET but not to the ARPA side. Did anybody on the ARPAnet receive it? If not, is anyone interested? I can either e-mail it or (if there is enough demand) post it again.

OmniCom is a vt100 emulator with 80-column display and support for kermit, xmodem, and plain ASCII data capture and send from file. Also, it has a handy "Print Screen" function for printing short messages. I have found it highly satisfactory for use with my VAX screen editor, and have not even needed to install a special termcap file -- it acts just like a real vt100 in almost all respects.

-John Sangster / jhs@mitre-bedford.arpa

GVGVGVGVGVGVGVGVGVGVGVGVGVGVGVGVGVGVGVGVGVGVGVGV

I don't know how to do it, but you ought to be able to use any
modem with
your 8 bit machine. I found out by accident that the 8-bit operating
system
which is built into the machine (i.e., it's there even if you don't have
a disk
drive)includes software for inputting and outputting data on the serial
port.
It follows the standard custom of sending the bytes out one bit at a
time on a
single pin. Incoming data is received on another pin of the serial
port. Each
byte is preceded by a start bit, and is followed by a stop bit, and the
data
bits are ordered least-significant-bit first, six more bits,
most-significant
bit last. This is standard asynchronous serial transmission with 8 data
bits,
one start bit, one stop bit, no parity. The baud rate is settable by
pokeing
the appropriate memory locations, and setting up the serial port for
asynchronous I/O is also done by pokeing appropriate codes into the
right
addresses. Sorry, I don't have the addresses or the values that must go
into
them. These can be found in the hardware manual, or other published
literature.You may have to write your own software to configure the port
and input and
output the data, unless your already have some program that interfaces
with a

modem or does terminal emulation.
On the hardware side, the voltage levels used by the serial port
are not
compatible with what a modem expects to see. The serial port operates
at TTL
levels: logic 0 = zero volts, logic 1 = 5 volts. The modem expects
RS-232
levels: logic 0 = +3 to +24 (I think) volts, logic 1 = -3 to -24 volts.
You
must provide the hardware to do the voltage level translation. The
easiest way
to do this is to use a chip such as the Maxim MAX232 which requires only
5 volts
and can be powered by the 5 v pin in the serial port itself. This chip
generates its own +9 and -9 volts for the RS232 levels and translates
incoming
RS232 levels to TTL levels. Only a few external components need to be
connected
to the chip (a few small capacitors and resistors) and the circuit is
very
simple (see MAX232 data sheet).
I'm amazed at the number of features that were included in the
original
8-bit machines that were not advertised or brought to the attention of
purchasers. Included at no additional expense were horizontal and
vertical
smooth and coarse scrolling, animation by page flipping, custom display
lists,
sprites, joystick ports that can be used for output as well as input,
paddle
ports that can accept photocell and resistance thermometer inputs, tone
generation for dialing touch tone phones, asynchronous serial port for
communicating with modems or other (multivendor) computers. And all
this stuff
was accessible through BASIC, worked with only 16kbits of memory, and
didn't
require a disk drive or expansion box.

Tramiel and many members of his staff have considered the 8-bit
machine, enhanced, as a competitor for the ST. Also the Game
machine image of the ATARI 8-bits machines does not seem to warrant
any type of upgrade. I have stated that i would support any
upgrades that ATARI would develope for the 8-bit. Besides a little
criticism never hurts. Tramiel does not take the 8-bit to seriously.
JWT and Landon Dyer are the most helpful people atari has on this
net.

Answer this question why did a ATARI try to block the release
of the PD 8-bit emulator for the ST????? Don't quote Propietary OS.

From: jhs@mitre-bedford.ARPA

A couple of weeks ago, I posted a new "shareware" version of CDY's OmniCom to the net. Unlike the original OmniCom, this version does not require the installation of the OMNIVIEW chip. I have the feeling it made it out to BITNET but not to the ARPA side. Did anybody on the ARPAnet receive it? If not, is anyone interested? I can either e-mail it or (if there is enough demand) post it again.

OmniCom is a vt100 emulator with 80-column display and support for kermit, xmodem, and plain ASCII data capture and send from file. Also, it has a handy "Print Screen" function for printing short messages. I have found it highly satisfactory for use with my VAX screen editor, and have not even needed to install a special termcap file -- it acts just like a real vt100 in almost all respects.

I don't know how to do it, but you ought to be able to use any modem with
your 8 bit machine. I found out by accident that the 8-bit operating system

which is built into the machine (i.e., it's there even if you don't have a disk
drive)includes software for inputting and outputting data on the serial port.
It follows the standard custom of sending the bytes out one bit at a time on a
single pin. Incoming data is received on another pin of the serial port. Each
byte is preceded by a start bit, and is followed by a stop bit, and the data
bits are ordered least-significant-bit first, six more bits, most-significant
bit last. This is standard asynchronous serial transmission with 8 data bits,
one start bit, one stop bit, no parity. The baud rate is settable by pokeing
the appropriate memory locations, and setting up the serial port for
asynchronous I/O is also done by pokeing appropriate codes into the right
addresses. Sorry, I don't have the addresses or the values that must go into
them. These can be found in the hardware manual, or other published
literature.You may have to write your own software to configure the port and input and
output the data, unless your already have some program that interfaces with a
modem or does terminal emulation.
On the hardware side, the voltage levels used by the serial port are not
compatible with what a modem expects to see. The serial port operates at TTL
levels: logic 0 = zero volts, logic 1 = 5 volts. The modem expects RS-232
levels: logic 0 = +3 to +24 (I think) volts, logic 1 = -3 to -24 volts. You
must provide the hardware to do the voltage level translation. The easiest way
to do this is to use a chip such as the Maxim MAX232 which requires only 5 volts
and can be powered by the 5 v pin in the serial port itself. This chip
generates its own +9 and -9 volts for the RS232 levels and translates incoming
RS232 levels to TTL levels. Only a few external components need to be connected
to the chip (a few small capacitors and resistors) and the circuit is very
simple (see MAX232 data sheet).
I'm amazed at the number of features that were included in the original
8-bit machines that were not advertised or brought to the attention of

purchasers. Included at no additional expense were horizontal and
vertical
smooth and coarse scrolling, animation by page flipping, custom display
lists,
sprites, joystick ports that can be used for output as well as input,
paddle
ports that can accept photocell and resistance thermometer inputs, tone
generation for dialing touch tone phones, asynchronous serial port for
communicating with modems or other (multivendor) computers. And all
this stuff
was accessible through BASIC, worked with only 16kbits of memory, and
didn't
require a disk drive or expansion box.

Subject: New Atari Hardware News
To: info-atari8@score.stanford.edu

The following is a collection of hardware announcements that I
have collected as a function of being the Admin for the Club
Network. I always try and keep the Club's 8-bit people abreat
of the latest news, so, while commercial in nature, this isn't
meant as an ad proper as much as a list of new hardware and
software that I have found for the 8-bit.

From Terrific Corp. I have received the following information
about this home control system:
"The X-10 POWERMANAGER SYSTEM

Now you can finally use your Atari Home Computer to conveniently
create, store and recall programs that can be loaded into the
X-10 PowerHouse controller to control lights, appliances and
other devices hooked up to X-10 control modules throughout your home.

There are two X-10 interface kits available from Terrific Corp.
One kit includes an X--10 PowerHouse Computer interface, a special
Atari interface adaptor and the Powermanager software. For those
who already have the PowerHouse computer interface, the software
and adaptor are available seperately.

The Powermanager software takes full advantage of the PowerHous
interface. Features include:

-Up to 256 modules can be individually controlled. Modules can be grouped
together to allow control of an 'infinite' number of devices.
-Lights and appliances can be programmed to turn on or off at specified
times through the use of a timer event schedule. In addition, lights
can be programmed to dim to 16 intenstities.
-Timer event schedules can hold up to 128 events, a single event can
control up to 16 modules.

-Timer event schedules can be created, stored and edited on disk.
-Modules can be controlled instantly from the Atari.
-Software allows use of joystick or keyboard
-48K required, machine language, drive.

Terrific Corp.
17 St Mary's Court
Brooklin, MA 02146
(617) 232-2317"

You all know these things. The dreaded BSR controller returns.
Actually, these really ARE cool. I have a friend with equivalent
software on his TRS Coco. It's all very impressive and neat.
The only problem is that control modules get expensive as you
wire up a whole house. He bought out an RS inventory at $3 a
module or so. The only way to do it.

More exciting Atari 8bit hardware came recently from the yet scarier
IRATA VERLAG corp. Their offerings included:

512K card for the 800XL....$170
512K special chip for use
with above card.....$52
Card and Chip together.....$200
6 OS System Box : Basically the equivalent of the RAM-ROD XL.
This allows you to have 6 diffeent OS chips and then to
select amongst them with a switch.
.....$50
HIGH CHIP: for people who have the Happy drive enhancement.
This chip has a hidden menu. Hold don select while you press
RESET and you get a menu with the options for COLD START,
SECTOR COPY, or TURN HAPPY ON/OFF. "Saves times."
.....$50
XE CHIP WITH RAMDISK.....$75 (doesn't say anything else!)
OLD SYS CHIP:
Replacement OS chip for XL/XE's for 400/800 compatibility
.....$???

All chips that have something to do with the Happy have a special
feature. For people who know machine language, the happy
can load any protected disk into the happy memory, then
turn around and write the binary data back onto a normal
formatted diskette. This allows you to then take a sector
editor to look at the actual bit stream from the original
disk to learn how it is set up.

Some new 8bit software:
100 New Print Shop pictures....$7
The Editor.....$15
The Super Label II.....$15

THE XL/XE SUPER TURBO INTERFACE:
This is a disk interface for the Atari 8bit that allows you
to do many different things. They are:
-Use IBM 5.25" and ST 3.5" disk drives for fast seek and large
storage capacities
-Back up ANY protected 8bit software
-Transfer between any of the three (Atari, IBM, 3. 5") formats.
-Backs up all protected ST & IBM software too!?
-Has built in 8bit pritnter interface
-For people with Happy drives, the SUPER TURBO works with the
Happy and kicks the baud rate to an awesome.......
(drum roll) * 150,000 * baud. It loads programs in 7 seconds
and does whole disk copies in 27 seconds. (THIS, I gotta see.)

SUPER TURBO INTERFACE.....$250

I am NOT affiliated with these people in any way. In fact,
I have absolutely no idea where they are or came from. I just
get a lot of release info in the process of searching out
what's new for Club Net 8bit owners and thought it might
interest some of the netters. The english on the IRATA
ad left something to be desired, so be sure and give these
guys the third degree when you call to make sure it is
ligit. Forgot to list their address/phone number. It's

IRATA VERLAG
1272B POTTER DRIVE
COLO SPRINGS, CO 80909
(303) 596-0135

I also talked to ICD today and they claimed that the SPARTADOS-X
cart would be available for Xmas.

Such is excitement. No news from the we fine brave souls in
the Turbo-project. We just got the 65802. Hope!

Terry Conklin
ihnp4!msudoc!conklin
Club Lansing (517) 372-3131 (gets all this junk first.)
Club II (313) 334-8877 (next day or so)
Club III (714) xxx-xxxx (at this rate, we may never know)
So this is what happens when BBS's go Imperialist. It becomes
some sort of public entity. Swell. Does that mean I have to
housebreak it?

591. Standalone (shareware) OmniCom

Newsgroup: comp.sys.atari.8bit
Date: 1987-10-04 03:47:45 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8710040347.AA08607@mitre-bedford.ARPA>
Source record: 117445

Steven Grove, your message arrived with no useable return path, so I am unable to reply directly.

Steve comments that he would like to download OmniCom but has no terminal software with which to download it. This situation keeps coming up. Can't somebody come up with a simple downloading program? The following program might be turned into something that can be used for this purpose by adding some machinery to buffer the received data in a string, then CLOSE the serial I/O and write the string to a file. Steve, maybe you could be the one to get this working. Meanwhile, the program below, as it stands, may be enough to let you at least log in as a dumb terminal. You may have to fiddle to get it working, but it is what Avatex publishes with their modem as a simple terminal program.

-John S.

592. XF551 and ADOS

Newsgroup: comp.sys.atari.8bit
Date: 1987-10-05 12:44:19 UTC
From: lazear@GATEWAY.MITRE.ORG
Message-ID: <8710051244.AA00214@saturn.mitre.org>
Source record: 117446

I have seen the XF551 advertized in ANTIC, but haven't seen any word on
the ADOS that supposedly accompanies it. You would think this would
be a big deal and worthy of a review. Anyone seen the drive for real
or used ADOS?
Walt Lazear (lazear@gateway.mitre.org)

593. Dhrystone figures for the Atari 800xl

Newsgroup: comp.sys.atari.8bit
Date: 1987-10-05 14:05:21 UTC
From: res@cblpe.ATT.COM
Message-ID: <647@cblpe.ATT.COM>
Source record: 117447

x
I recently ported the Dhrystone Version 1.1 software to my Atari 800xl
and compiled it using the CC8 compiler recently posted by Steve Kennedy.
I then recoded the program in the Action! language and ran it. Here
are the results:

CC8 Version 2.3b, Ace-C Runtime Engine: 7.8 dhrystones/sec
Action! Version 3.6: 131 dhrystones/sec

By way of comparison here are how some other common micro's performed:

Commodore 64, C Power 2.9 trim: 34 dhrystones/sec
Commodore 128, C Power 128 trim: 68 dhrystones/sec
IBM PC/XT, MS-DOS 2.0, Microsoft 3.1 C: 347 dhrystones/sec
Atari 520ST, TOS, Lattice 3.03.01: 450 dhrystones/sec
Amiga 1000, Manx C 2.30a, 32 bits: 684 dhrystones/sec
Amiga 1000, Manx C 2.30a, 16 bits: 915 dhrystones/sec
Atari 520ST, TOS, Megamax 1.0: 1136 dhrystones/sec
IBM PC/AT, PC-DOS 3.20, Microsoft 4.0: 1796 dhrystones/sec

Comments:
The dhrystone program is designed to generate a "figure of merit" benchmark
of a particular computer / compiler combination. It consists of a
statistically typical set of operations, minus i/o and floating point,
invoked repeatedly and timed. The results are indicated in iterations/sec.
Published statistics exist for literally hundreds of machine/compiler
combinations.

In getting these programs to run, I had to make several modifications, which
I believe did not significantly alter the final results. Since CC8 does not
recognize 'typedefs', I had to rewrite the code so as not to use them.
Action!, of course, is an entirely different language, but I took care
to port the code faithfully. Surprisingly, the only area where I had trouble
making a direct port involved a doubly dimensioned array. Action! does not
support this, so I had to define a large singly dimensioned array and generate
the index manually. The dhrystone package was, by design I believe,
not optimally written in C, and could have been made for efficient during
the rewrite, if that had been a goal.

The results speak well of the machine and compilers. CC8 is a real jewel,
the best C compiler I have seen for the Atari, and Steve has taken pains
to include most of the constructs found in the full implementation of C.
This was substantiated by the ease of the port. However, CC8 is interpretive,
so you would not expect it to be a stellar performer in the speed category.

Action! is marketed by OSS, Inc., and is a true compiler plus development system on a plug-in Atari cartridge. Not only does it possess a phenominal human interface, but the code it produces is well known to run like a bat out of hell. Too bad it is a language which has never been available on anything but the 8-bit Ataris. One concern I had was that Action! stores string variables internally in a different format from C. I don't think this is significant in the operation of the program, so I did not go out of my way to try to mimic C here, but rather let Action do its thing.

I never expected to break 100 dhrystones/sec even if I coded in assembler. To do this on an 8-bit machine with a clock speed of less than 2 Mhz is truely impressive. I did not try a port to Basic, but it would be interesting to see what kind of figures this would produce. Any takers?

594. Re: Critcism or Embarassment,ATARI corp?

Newsgroup: comp.sys.atari.8bit
Date: 1987-10-05 17:50:24 UTC
From: neil@atari.UUCP
Message-ID: <863@atari.UUCP>
Source record: 117448

In article <8710012029.AA22072@ucbvax.Berkeley.EDU>, DFLINT02@ULKYVX.BITNET writes:

> Answer this question why did a ATARI try to block the release
> of the PD 8-bit emulator for the ST????? Don't quote Propietary OS.

The answer is easy. We didn't. Contrary to popular rumor/reports, Darek's biggest problem when getting ready to release the emulator was getting through to the right person here. He ended up with myself and Richard Frick. We took the story to Sam Tramiel, President of Atari Corp. The three of us agreed that we had no problem allowing the release of the emulator, but in return for this we wanted Darek to release his source code as public domain. The emulator as it currently exists is too slow to be useful, not to mention the lack of support for important features like player/missile graphics.

At any rate, Darek was reluctant to do this at first. He seemed to want sole credit for the emulator. The impasse was resolved on GEnie, in a series of messages between Darek and myself with audience participation. Then Darek asked for permission to sell an article on the emulator to an ST magazine so he could make a little money for the project. This was granted. The emulator was recently published in ST-Log magazine (September issue) and is available for download on GEnie and other places.

These days, Darek is getting along with Atari a little better. I think he's not a bad negotiator -- he was stirring up public sympathy for himself in order to get what he wanted from us. On the other hand, we got the source code released, so we're happy too. Let's hope that the project ends up resulting in an emulator that does what we all want it to do.

I have a little problem. I would like to have a copy of kermit on my atari but have no way of down loading it to the atari. I would be willing to mail a disk and a stamped mailer if some one would be willing to copy it for me. Thanks in advance

Dave Pryor davidp@tc.fluke.COM

596. some silly programs

Newsgroup: comp.sys.atari.8bit
Date: 1987-10-06 02:48:52 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8710060248.AA27047@mitre-bedford.ARPA>
Source record: 117450

Probably everybody who ever got a home computer must have written one of each of the following programs, but I thought a few readers of these postings might find them useful nevertheless, especially "APRPROG.BAS", which computes the effective Annual Percentage Rate of a loan.

-John Sangster / jhs@mitre-bedford.arpa

```
------------------------------------------------------------------------------
MORTGAGE.BAS - Simple loan payment calculator. Given the Annual Percentage
Rate of interest, the number of payments per year (normally 12), and the total
number of PAYMENTS in which loan is to be paid off, returns the monthly
payment amount. (E.g. for 30 years of monthly payments, there are 360
payments.) The above is obtained by "RUN" or GOTO 100. If you start the
program instead with "GOTO 400", it prints, on your printer, a table of
"dollars per thousand" loan amounts for a range of interest rates you select
and for a set of convenient loan durations (15, 20, 25, 30 years). (C) 1987

597. SX212 info sought

Newsgroup: comp.sys.atari.8bit
Date: 1987-10-06 03:32:01 UTC
From: wilmott@topaz.rutgers.edu
Message-ID: <15362@topaz.rutgers.edu>
Source record: 117451

!!!!!!!!!!!!!!!!!!!!!!!!!!!!

Hello all. Rumour has it in these parts that the SX212 will
be on stores shelves very soon (if it isn't already!). A couple
questions maybe someone out there can answer for me that none
of my friends seems to know for sure...

1) Can you or can you not connect the SX212 directly to the 8-bit
without an interface?
2) About connecting to the 8-bit, does it come packaged with
the necessary cable and term program (I'd heard something
about a new version of Express?), or do you have to hunt
them down seperately?
3) Perhaps most importantly to me, since the main reason I would
like to get the SX212 is for use with the schools' Unix system
(300 baud can be painful when you want to do something other than
read the newsgroups :-)), I would like to know *for sure* if
Chameleon will work with it or not.

As always, any info is greatly appreciated.

-Ray Wilmott

to return from a program to DOS? I always thought the protocol was that DOS (any DOS) effectively JSR'ed to the start address of the program once it was loaded; thus the right way to return was just to RTS. That's always worked for me, using DOS XL. However, I've gotten some reports that Kermit-65 sometimes wedges up when one exits from it. I'm pretty sure I'm not trashing the stack; it really looks like DOS expects something other than an RTS.

Anyone got any ideas? Thanks in advance.

599. November 1987 ANTIC TOC

NOVEMBER 1987 ANTIC TOC
Theme: PRACTICAL APPLICATION WINNERS

page article

7 I/O BOARD
Letters from Readers.
7 DISK BONUS PROGRAM
The bonus this month is GALLEONS, an arcade quality sea
battle. It is described as a flashy, colorful two-player
action game. ML.
13 PRODUCT REVIEWS
Software
Money$pin (White Bag Software)
Hardware
Animation Station (Suncom)--A touch tablet that comes with
DesignLab paint program.
20 NEW PRODUCTS
A description but not a review of several new products
available for the Atari computers. This month announcements
include Pirates of the Barbary Coast, Aliants, Sprong, Space
Lobster & Disk 50 (all Star Soft); Smart Speaker (Swisscomp,
Inc); Guild of Thieves (Firebird); Borodino:1812 (KRENtek
Software) and Ace of Aces (Accolade).
29 GAME OF THE MONTH: HOT AND COLD
A classic peg game similar to Master Mind.
35 GRAND PRIZE APPLICATION WINNER: CRITICAL-PATH PROJECT MANAGER
Design your own project time line. Display and print out
information in various forms including a GANT chart.
37 GRAND PRIZE APPLICATION WINNER: WYSIWYG CASSETTE JACKETS
Do you record your own music or copy your records onto a
cassette tape? This program allows you to design a cassette
jacket that can be cut to fit in a standard case. Designed
to work with Epson compatible printers.
39 GRAND PRIZE APPLICATION WINNER: YOUR BEST ROUTE
Planning a trip? Use this program to build a chart that
lists distances between all cities you plan to visit and
then let the program tell you the shortest route to take
to see all the points of interest.
40 GRAND PRIZE APPLICATION WINNER: BIBLIOGRAPHY MASTER
This programs allows you to edit and print bibliographies
for all those term papers you have to write.
46 LAPTOP-TO-ATARI CONNECTION

This article explains how to move information from a laptop computer such as a Radio Shack Model 100 to your Atari.

**********BEGIN THE ST RESOURCE SECTION**********

63 SOFTWARE LIBRARY
This section contains all the program listings for the articles in this issue.
82 TECH TIPS
This section is a collection of tips and short programs from readers or collected from various Users Groups newsletters.

Coming next month:

Comments: The Catalog (that comes bound in the magazine) is a new issue this month. They have several new ST programs or new versions (such as Flash 1.5) and several bargains for both the 8bit and ST owners. ANTIC claims they ship within 24 hours and I tend to believe them. I got my order in less than a week after placing an order. There is an ad for a new OS for the 8bit XL/XE machines called the EXPANDER (Synergy Concepts) that sounds like it would be really nice for several types of applications. Anyone ever had any personal experience with it? The E. Arthur Brown Company have a full page an in this issue. They make the ST Video Box, ST Composite Cable and a ST Solderless RAM upgrade kit, among other things.

I have had similar problems with various communications programs,
including a very simple one I wrote years ago in basic. I formed the
conjecture that there are mysterious problems which arise after turning
on concurrent io mode in an 850 interface. Does anyone know anything about
this?

I recently discovered instructions for constructing a write-only RS232 interface for the atari using (as ever) one of the joystick ports. Is there anyone out there who knows of an assembly language listing of a full RS232 serial interface using the second joystick port which they could email ?

Also would it be possible to alter any of the terminal emulators available on the net to use such an interface (i.e substitute the joystick port RS232 handler for the emulator's original handler) ?

From: jhs@mitre-bedford.ARPA

Steven Grove, your message arrived with no useable return path, so I am unable
to reply directly.

Steve comments that he would like to download OmniCom but has no terminal
software with which to download it. This situation keeps coming up. Can't
somebody come up with a simple downloading program? The following program
might be turned into something that can be used for this purpose by
adding some machinery to buffer the received data in a string, then
CLOSE the serial I/O and write the string to a file. Steve, maybe you
```

could be the one to get this working. Meanwhile, the program below, as
it stands, may be enough to let you at least log in as a dumb terminal.
You may have to fiddle to get it working, but it is what Avatex publishes
with their modem as a simple terminal program.

-John S.

```
------------------------------c-u-t---h-e-r-e--------------------------------

Subject: some silly programs
Date: Mon, 05 Oct 87 22:48:52 EDT
From: jhs@mitre-bedford.ARPA

Probably everybody who ever got a home computer must have written one of each of the following programs, but I thought a few readers of these postings might find them useful nevertheless, especially "APRPROG.BAS", which computes the effective Annual Percentage Rate of a loan.

-John Sangster / jhs@mitre-bedford.arpa

MORTGAGE.BAS - Simple loan payment calculator. Given the Annual Percentage Rate of interest, the number of payments per year (normally 12), and the total number of PAYMENTS in which loan is to be paid off, returns the monthly payment amount. (E.g. for 30 years of monthly payments, there are 360 payments.) The above is obtained by "RUN" or GOTO 100. If you start the program instead with "GOTO 400", it prints, on your printer, a table of "dollars per thousand" loan amounts for a range of interest rates you select and for a set of convenient loan durations (15, 20, 25, 30 years). (C) 1987 by John H. Sangster, placed in the public domain for non-commercial use; all commercial rights reserved.

Date: 5 Oct 87 14:05:21 GMT
From: cbosgd!cblpf!cblpe!res@ucbvax.Berkeley.EDU (Rob Stampfli)
Subject: Dhrystone figures for the Atari 800xl
To: info-atari8@score.stanford.edu

x
I recently ported the Dhrystone Version 1.1 software to my Atari 800xl
and compiled it using the CC8 compiler recently posted by Steve Kennedy.
I then recoded the program in the Action! language and ran it. Here
are the results:

CC8 Version 2.3b, Ace-C Runtime Engine: 7.8 dhrystones/sec
Action! Version 3.6: 131 dhrystones/sec

By way of comparison here are how some other common micro's performed:

Commodore 64, C Power 2.9 trim: 34 dhrystones/sec
Commodore 128, C Power 128 trim: 68 dhrystones/sec
IBM PC/XT, MS-DOS 2.0, Microsoft 3.1 C: 347 dhrystones/sec
Atari 520ST, TOS, Lattice 3.03.01: 450 dhrystones/sec
Amiga 1000, Manx C 2.30a, 32 bits: 684 dhrystones/sec
Amiga 1000, Manx C 2.30a, 16 bits: 915 dhrystones/sec
Atari 520ST, TOS, Megamax 1.0: 1136 dhrystones/sec
IBM PC/AT, PC-DOS 3.20, Microsoft 4.0: 1796 dhrystones/sec

Comments:
The dhrystone program is designed to generate a "figure of merit" benchmark of a particular computer / compiler combination. It consists of a statistically typical set of operations, minus i/o and floating point, invoked repeatedly and timed. The results are indicated in iterations/sec. Published statistics exist for literally hundreds of machine/compiler combinations.

In getting these programs to run, I had to make several modifications, which I believe did not significantly alter the final results. Since CC8 does not recognize 'typedefs', I had to rewrite the code so as not to use them. Action!, of course, is an entirely different language, but I took care to port the code faithfully. Surprisingly, the only area where I had trouble making a direct port involved a doubly dimensioned array. Action! does not support this, so I had to define a large singly dimensioned array and generate the index manually. The dhrystone package was, by design I believe, not optimally written in C, and could have been made for efficient during the rewrite, if that had been a goal.

The results speak well of the machine and compilers. CC8 is a real jewel, the best C compiler I have seen for the Atari, and Steve has taken pains to include most of the constructs found in the full implementation of C. This was substantiated by the ease of the port. However, CC8 is interpretive, so you would not expect it to be a stellar performer in the speed category.

Action! is marketed by OSS, Inc., and is a true compiler plus development system on a plug-in Atari cartridge. Not only does it possess a phenominal human interface, but the code it produces is well known to run like a bat out of hell. Too bad it is a language which has never been available on anything but the 8-bit Ataris. One concern I had was that Action! stores string variables internally in a different format from C. I don't think this is significant in the operation of the program, so I did not go out of my way to try to mimic C here, but rather let Action do its thing.

I never expected to break 100 dhrystones/sec even if I coded in assembler. To do this on an 8-bit machine with a clock speed of less than 2 Mhz is truely impressive. I did not try a port to Basic, but it would be interesting to see what kind of figures this would produce. Any takers?

Subject: SX212 info sought
To: info-atari8@score.stanford.edu

!!!!!!!!!!!!!!!!!!!!!!!!!!!

Hello all. Rumour has it in these parts that the SX212 will
be on stores shelves very soon (if it isn't already!). A couple
questions maybe someone out there can answer for me that none
of my friends seems to know for sure...

1) Can you or can you not connect the SX212 directly to the 8-bit
without an interface?
2) About connecting to the 8-bit, does it come packaged with
the necessary cable and term program (I'd heard something
about a new version of Express?), or do you have to hunt
them down seperately?
3) Perhaps most importantly to me, since the main reason I would
like to get the SX212 is for use with the schools' Unix system
(300 baud can be painful when you want to do something other than
read the newsgroups :-)), I would like to know *for sure* if
Chameleon will work with it or not.

As always, any info is greatly appreciated.

to return from a program to DOS? I always thought the protocol was that
DOS (any DOS) effectively JSR'ed to the start address of the program
once it was loaded; thus the right way to return was just to RTS.
That's always worked for me, using DOS XL. However, I've gotten some
reports that Kermit-65 sometimes wedges up when one exits from it. I'm
pretty sure I'm not trashing the stack; it really looks like DOS expects
something other than an RTS.

Anyone got any ideas? Thanks in advance.

From: ehs@jumbo.dec.com
Message-ID: <973@jumbo.dec.com>
Source record: 117458

About a week ago, I posted a three-part message about VT52B, a simple emulator for an extended VT52 that I have found useful for talking to Unix. I have since heard from two people who got the first two parts but not the third (the ACTION! code itself).

If anyone else wants this, drop me a note with a clear return address and I'll try to send it directly. It's about 14K bytes.

> ...

What a noble thought. I think the idea of releasing source code is great.

Did this idea come from the same company which has steadfastly refused
to release (or even to acknowledge requests for) the source for the XL
operating system? How much better a world this would be if the left hand
and the right hand could agree on the goodness value of things.

Note that I am not suggesting that the OS source be put in the public domain,
only that source should be available. Of course I can disassemble the ROMs
(and have done so), and most of what I want to know can be extracted that
way. It just hurts to think of the more productive things I could have
with that time!

Going to DOS from any communications program
that uses the 850 R: handler is big trouble.
DUP.SYS loads right over the handler itself, so
that when you return to the program the R: device
is gone.
If you're using OS/A+, DOS XL, or SpartaDOS these
caveats may not apply. But it sure occurs with
Atari DOS 2.X

A friend of mine who is an elementery school teacher (w/o net access, of course) asked me to post this for him. You can e-mail me, or call him.

Hello, my name is Brett Wyatt, and I teach a class of fourth graders. I am trying to set up a computer lab for my class, and I can use a donation of almost anything you can mention. In particular, I need the 16 to 32 k expansion units for the Atari 400's, disk drives for the TRS 80 Color Computer, any sort of running IBM PC or Apple type computer, printers (old Decwriters would be *GREAT*) and educational software, like a tutorial building language and math/spelling games. General purpose software like a communications program and programming languages would be good for the more advanced students as well.

Thank you very much. Of course, all donations would be tax deductable. Please call me at (916) 758-4165 or respond via e-mail.

Are you using Action? Action writes object files based off the Init
vector. Unfortunately, it also provides a valid address for the Run vector.
What happens is that an Action program will load, execute, and then DOS
will try to execute it again based on the Run vector. (The two addresses
here aren't identical - the Init vector points to some runtime startup
code, whereas the Run vector points to the actual beginning of the program.)
The solution is simple - Define a global variable at the beginning of
your program, and pre-initialize it to the value $60. As long as the first
byte of your program is an RTS, things should work fine...

611. Atari program files

Newsgroup: comp.sys.atari.8bit
Date: 1987-10-09 17:33:26 UTC
From: vaughan@canisius.UUCP
Message-ID: <1781@canisius.UUCP>
Source record: 117465

I have seen many messages telling us that a nice compiler or
such has been posted, or better yet is available on some arpa
node. Question: Where are you posting this stuff? It isn't
in the news gorup, not in the archives at Canad01 of Finhut.
Alot of us do not have arpa access so ftp is out. So can
someone tell me how to get this stuff?

At this time I am really interested in the CC8 c compiler, and
the latest version of kermit65. I am on bitnet and uucp.
Also what is archived at info-atari@score for the 8bit. And how
do we get it.

Reply to me using email or post it, this digest comes to me on
bitnet, and I readnews once in a while1

thankS

With the growing number of programs in this news group does anybody know if it would be possible to archive these files at database@bitnic? This is supposed to be an internetwork database. The digests are fairly common and are redunantly archieved at several nodes on bitnet, but the usable code and utilities are in accessable to only arpanet users.

>
>f1.gdm @ isumvs.bitnet

This should be quite simple. I have never seen a ramrod or similar board,
or tried this myself.

Piggyback the two ROMs. All pins except 20 (chip enable) and 22 (output
enable) can be connected directly. I will outline four possibilities for
hooking up the select logic, each with its own set of advantages and dis-
advantages.
I would leave as much airspace as practical between the two ROMs.

Note: This is based on information about 27128 EPROMs. While these schemes
should work with ROMs, I do not know if they have the same poser-saving
circuitry in them that the EPROMs have.
27128 EPROMs draw 100mA in active mode (CS/ low), 25mA in standby mode
(CS/ high). The outputs are enabled only if CS/ and OE/ are both low.

1. Wire both pin 20s together, and connect to pin 20 on socket. Wire up a
switch so that one pin 22 is grounded, the other pulled to +5V.
Advantage: Only DC on switch.
Disadvantage: Both ROMs will go from standby to active whenever the ROM is
addressed.

2. same as one, but with pins 20 and 22 reversed.
Advantage: Only DC on switch.
Disadvantage: The switch-selected ROM will always be in active state

3. Pins 22 connected to each other and board. Wire up a switch so that
the signal from pin 20 on the board is fed to pin 20 of one ROM, while
pin 20 of the other is pulled to +5V.

Advantage: Only the selected ROM is active, and only when needed.
Disadvantage: Chip enable signal on switch and wiring, placement and construction are more critical.

4. By using suitable gates you can create the effect of solution 3, but without the drawback of having high-speed signals running to and through your switch.
Disadvantage: More complex.

Personally I would recommend solution 3, unless you want the switch outside the case, in which case I would recommend solution 2.

615. OmniCom

Newsgroup: comp.sys.atari.8bit
Date: 1987-10-12 15:07:46 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8710121507.AA01059@mitre-bedford.ARPA>
Source record: 117469

Several people have sent me questions about OmniCom which make me think that not everyone will realize that the basic OmniCom program needs to be linked together with an RS-232 handler to make it work. In particular, with the 1030 and 835 direct-connect modems, not all the handlers floating around work exactly right. There is a special one called ATARISRS.232 which is 16 sectors long which will work OK with the 850 interface as well as the 1030 and 835 direct-connect modems. This handler is shipped on the disk with OmniCom, so if you've been having trouble making OmniCom work with an 835 or 1030, but would like a terminal emulator with all its features, you should probably go ahead and order it on disk from CDY.

If you have a handler sitting around but don't know what to do with it, make a disk with DOS on it, and make a copy of the handler on that disk, but name it "OC" (for OmniCom). They copy the OmniCom shareware program onto the end of it using the DOS "append" mode, like this:

C<RETURN>
D1:OC.OBJ, D2:OC/A<RETURN>

or the equivalent using your favorite DOS. With DOS 2.0 or 2.5, the "/A" on the end of the destination filename makes DOS append the source file to the end of the existing destination file, instead of writing over it as it would if you failed to specify /A.

The result is a file containing the RS232 handler, followed immediately by the OmniCom program. This should now run properly, assuming the RS232 handler is suitable for your modem interface.

-John Sangster / jhs@mitre-bedford.arpa

616. 192K upgrade

Newsgroup: comp.sys.atari.8bit

Yes, the modem is already being sold (at least at dealers here in Northern
California).

> 1) Can you or can you not connect the SX212 directly to the 8-bit
> without an interface?
Yes. The SX212 has an Atari SIO connector on its rear panel. It will work
with an R-verter type handler that is available on Compuserve.

> 2) About connecting to the 8-bit, does it come packaged with
> the necessary cable and term program (I'd heard something
> about a new version of Express?), or do you have to hunt
> them down seperately?
No. SX-Express (based on the older 850-Express) will be offered separately.
An SIO cable will be packaged with that program. SX-Express is currently in
software test.

> 3) ...I would like to know *for sure* if Chameleon will work with it or not.
At the moment, the only way you could be *sure* that it will work with
Chameleon would be to use it connected to an 850 the way people have been
using Hayes compatible modems for years.

I have had similar problems with various communications programs, including a very simple one I wrote years ago in basic. I formed the conjecture that there are mysterious problems which arise after turning on concurrent io mode in an 850 interface. Does anyone know anything about this?

Theme: PRACTICAL APPLICATION WINNERS

page article

7 I/O BOARD
Letters from Readers.
7 DISK BONUS PROGRAM
The bonus this month is GALLEONS, an arcade quality sea battle. It is described as a flashy, colorful two-player action game. ML.
13 PRODUCT REVIEWS
Software
Money$pin (White Bag Software)
Hardware
Animation Station (Suncom)--A touch tablet that comes with DesignLab paint program.
20 NEW PRODUCTS
A description but not a review of several new products available for the Atari computers. This month announcements include Pirates of the Barbary Coast, Aliants, Sprong, Space Lobster & Disk 50 (all Star Soft); Smart Speaker (Swisscomp, Inc); Guild of Thieves (Firebird); Borodino:1812 (KRENtek Software) and Ace of Aces (Accolade).
29 GAME OF THE MONTH: HOT AND COLD
A classic peg game similar to Master Mind.
35 GRAND PRIZE APPLICATION WINNER: CRITICAL-PATH PROJECT MANAGER
Design your own project time line. Display and print out information in various forms including a GANT chart.
37 GRAND PRIZE APPLICATION WINNER: WYSIWYG CASSETTE JACKETS
Do you record your own music or copy your records onto a

cassette tape? This program allows you to design a cassette
jacket that can be cut to fit in a standard case. Designed
to work with Epson compatible printers.
39 GRAND PRIZE APPLICATION WINNER: YOUR BEST ROUTE
Planning a trip? Use this program to build a chart that
lists distances between all cities you plan to visit and
then let the program tell you the shortest route to take
to see all the points of interest.
40 GRAND PRIZE APPLICATION WINNER: BIBLIOGRAPHY MASTER
This programs allows you to edit and print bibliographies
for all those term papers you have to write.
46 LAPTOP-TO-ATARI CONNECTION
This article explains how to move information from a laptop
computer such as a Radio Shack Model 100 to your Atari.

63 SOFTWARE LIBRARY
This section contains all the program listings for the
articles in this issue.
82 TECH TIPS
This section is a collection of tips and short
programs from readers or collected from various Users
Groups newsletters.

Coming next month:

Comments: The Catalog (that comes bound in the magazine) is a new issue
this month. They have several new ST programs or new versions
(such as Flash 1.5) and several bargains for both the 8bit and
ST owners. ANTIC claims they ship within 24 hours and I tend
to believe them. I got my order in less than a week after placing
an order. There is an ad for a new OS for the 8bit XL/XE
machines called the EXPANDER (Synergy Concepts) that sounds like
it would be really nice for several types of applications.

Anyone ever had any personal experience with it? The E. Arthur
Brown Company have a full page an in this issue. They make
the ST Video Box, ST Composite Cable and a ST Solderless RAM
upgrade kit, among other things.

> Answer this question why did a ATARI try to block the release
> of the PD 8-bit emulator for the ST????? Don't quote Propietary OS.

The answer is easy. We didn't. Contrary to popular rumor/reports, Darek's
biggest problem when getting ready to release the emulator was getting
through to the right person here. He ended up with myself and Richard Frick.
We took the story to Sam Tramiel, President of Atari Corp. The three of us
agreed that we had no problem allowing the release of the emulator, but in
return for this we wanted Darek to release his source code as public domain.
The emulator as it currently exists is too slow to be useful, not to mention
the lack of support for important features like player/missile graphics.

At any rate, Darek was reluctant to do this at first. He seemed to want
sole credit for the emulator. The impasse was resolved on GEnie, in a
series of messages between Darek and myself with audience participation.
Then Darek asked for permission to sell an article on the emulator to an ST
magazine so he could make a little money for the project. This was granted.
The emulator was recently published in ST-Log magazine (September issue) and
is available for download on GEnie and other places.

These days, Darek is getting along with Atari a little better. I think he's
not a bad negotiator -- he was stirring up public sympathy for himself in
order to get what he wanted from us. On the other hand, we got the source
code released, so we're happy too. Let's hope that the project ends up
resulting in an emulator that does what we all want it to do.

To: INFO-ATARI8@score.stanford.edu

I recently discovered instructions for constructing a write-only RS232 interface for the atari using (as ever) one of the joystick ports. Is there anyone out there who knows of an assembly language listing of a full RS232 serial interface using the second joystick port which they could email ?

Also would it be possible to alter any of the terminal emulators available on the net to use such an interface (i.e substitute the joystick port RS232 handler for the emulator's original handler) ?

Subject: re: VT52B, Yet Another Terminal Emulator
To: info-atari8@score.stanford.edu

About a week ago, I posted a three-part message about VT52B, a simple emulator for an extended VT52 that I have found useful for talking to Unix. I have since heard from two people who got the first two parts but not the third (the ACTION! code itself).

If anyone else wants this, drop me a note with a clear return address and I'll try to send it directly. It's about 14K bytes.

Posted-From: The MITRE Corp., Bedford, MA
To: info-atari8@score.stanford.edu
Subject: OmniCom
Date: Mon, 12 Oct 87 11:07:46 EDT
From: jhs@mitre-bedford.ARPA

Several people have sent me questions about OmniCom which make me think that not everyone will realize that the basic OmniCom program needs to be linked together with an RS-232 handler to make it work. In particular, with the 1030 and 835 direct-connect modems, not all the handlers floating around work exactly right. There is a special one called ATARISRS.232 which is 16 sectors long which will work OK with the 850 interface as well as the 1030 and 835 direct-connect modems. This handler is shipped on the disk with OmniCom, so if you've been having trouble making OmniCom work with an 835 or 1030, but would like a terminal emulator with all its features, you should probably go ahead and order it on disk from CDY.

If you have a handler sitting around but don't know what to do with it, make a disk with DOS on it, and make a copy of the handler on that disk, but name it "OC" (for OmniCom). They copy the OmniCom shareware program onto the end of it using the DOS "append" mode, like this:

C<RETURN>
D1:OC.OBJ, D2:OC/A<RETURN>

or the equivalent using your favorite DOS. With DOS 2.0 or 2.5, the "/A" on the end of the destination filename makes DOS append the source file to the end of the existing destination file, instead of writing over it as it would if you failed to specify /A.

The result is a file containing the RS232 handler, followed immediately by the OmniCom program. This should now run properly, assuming the RS232 handler is suitable for your modem interface.

> (E-Mail please)

Yes.

And now the modem question: My dad recently bought a 300 baud modem
for $8.95 from the back shelf of a computer store in town. It's
called "The Pocket Modem" and it was made by the same people who
made APE FACE (I believe they're out of business now). The modem plugs
directly into the serial port of the disk drive. It seems to work
just fine and my dad has had a great time calling up the local bulletin
boards. Now he'd like to try it with other modem software, but it
doesn't seem to have a handler--everything's hardcoded in the
software that came with the modem. He'd be willing to write a CIO
handler for it, but he really doesn't know what the modem commands are
(other than by disassembling the modem software). So, does anyone know
anything at all about this modem?

Thanks!

Steve Kennedy {moss,ihnp4,decwrl}!cbosgd!smk

> about a new version of Express?), or do you have to hunt
> them down seperately?
No. SX-Express (based on the older 850-Express) will be offered separately. An SIO cable will be packaged with that program. SX-Express is currently in software test.

> 3) ...I would like to know *for sure* if Chameleon will work with it or not.
At the moment, the only way you could be *sure* that it will work with Chameleon would be to use it connected to an 850 the way people have been using Hayes compatible modems for years.

I too would appreciate receiving the old 800 version of TurboBasic.
Could someone Please mail it to me and thanks in advance.

Subject: 192K upgrade
To: info-atari8@score.stanford.edu

I'm looking for docs to upgrade a 130XE to 192K RAM. I know they exist,
but haven't seen them. I'd like to stay away from 320K or 576K on this one
(I have one with 576K already). If you have them, I'd appreciate a copy!
Thanks in advance.

On the same subject, has anyone hacked a Freddie chip into a 256K 800XL to
get the extended video modes?

> Hello all. Rumour has it in these parts that the SX212 will
> be on stores shelves very soon (if it isn't already!).
Yes, the modem is already being sold (at least at dealers here in Northern California).

> 1) Can you or can you not connect the SX212 directly to the 8-bit
> without an interface?
Yes. The SX212 has an Atari SIO connector on its rear panel. It will work with an R-verter type handler that is available on Compuserve.

> 2) About connecting to the 8-bit, does it come packaged with
> the necessary cable and term program (I'd heard something
> about a new version of Express?), or do you have to hunt
> them down seperately?
No. SX-Express (based on the older 850-Express) will be offered separately. An SIO cable will be packaged with that program. SX-Express is currently in software test.

> 3) ...I would like to know *for sure* if Chameleon will work with it or not.
At the moment, the only way you could be *sure* that it will work with Chameleon would be to use it connected to an 850 the way people have been using Hayes compatible modems for years.

> (E-Mail please)

Yes.

And now the modem question: My dad recently bought a 300 baud modem
for $8.95 from the back shelf of a computer store in town. It's
called "The Pocket Modem" and it was made by the same people who
made APE FACE (I believe they're out of business now). The modem plugs
directly into the serial port of the disk drive. It seems to work
just fine and my dad has had a great time calling up the local bulletin
boards. Now he'd like to try it with other modem software, but it
doesn't seem to have a handler--everything's hardcoded in the
software that came with the modem. He'd be willing to write a CIO
handler for it, but he really doesn't know what the modem commands are
(other than by disassembling the modem software). So, does anyone know
anything at all about this modem?

Thanks!

192K upgrade
Re: SX212 info sought
Re: Ace C + a modem question
Re: Old 800 Turbo Basic

------------------------------------------------------------------------

Date: 13 Oct 87 18:58:05 GMT
From: oliveb!dragon@hplabs.hp.com (Give me a quarter or I'll touch you)
Subject: 192K upgrade
To: info-atari8@score.stanford.edu

I'm looking for docs to upgrade a 130XE to 192K RAM. I know they exist,
but haven't seen them. I'd like to stay away from 320K or 576K on this one
(I have one with 576K already). If you have them, I'd appreciate a copy!
Thanks in advance.

On the same subject, has anyone hacked a Freddie chip into a 256K 800XL to
get the extended video modes?

> Hello all. Rumour has it in these parts that the SX212 will
> be on stores shelves very soon (if it isn't already!).
Yes, the modem is already being sold (at least at dealers here in Northern California).

> 1) Can you or can you not connect the SX212 directly to the 8-bit
> without an interface?
Yes. The SX212 has an Atari SIO connector on its rear panel. It will work with an R-verter type handler that is available on Compuserve.

> 2) About connecting to the 8-bit, does it come packaged with
> the necessary cable and term program (I'd heard something
> about a new version of Express?), or do you have to hunt
> them down seperately?
No. SX-Express (based on the older 850-Express) will be offered separately. An SIO cable will be packaged with that program. SX-Express is currently in software test.

> 3) ...I would like to know *for sure* if Chameleon will work with it or not.
At the moment, the only way you could be *sure* that it will work with Chameleon would be to use it connected to an 850 the way people have been using Hayes compatible modems for years.

> (E-Mail please)

Yes.

And now the modem question: My dad recently bought a 300 baud modem
for $8.95 from the back shelf of a computer store in town. It's
called "The Pocket Modem" and it was made by the same people who
made APE FACE (I believe they're out of business now). The modem plugs
directly into the serial port of the disk drive. It seems to work
just fine and my dad has had a great time calling up the local bulletin
boards. Now he'd like to try it with other modem software, but it
doesn't seem to have a handler--everything's hardcoded in the
software that came with the modem. He'd be willing to write a CIO
handler for it, but he really doesn't know what the modem commands are
(other than by disassembling the modem software). So, does anyone know
anything at all about this modem?

Thanks!

633. Track-Ball Code! Basic And ACTION! ex.

Newsgroup: comp.sys.atari.8bit
Date: 1987-10-16 14:00:00 UTC
From: DFLINT02@ULKYVX.BITNET
Message-ID: <8710161846.AA17021@ucbvax.Berkeley.EDU>
Source record: 117487

Taming your machine with a mouse has long been a dream of the ATARI 8-bitters. The mouse had it's origins around the 1960's, but did see much use until the 1980's when the Mac,ST and Amiga were unveiled. The mouse was also used by the engineering world as an input device for graphics workstations in the late 70's. The Track-ball is a close relative to the Mouse. A track-ball is basicly the same device flipped over allowing the hand position the ball directly.

The Old ATARI did have some foresight in developing input devices for the 8-bit machines. The TrackBall is one of them. The Track-ball allows smooth tracking of 2 dimensional motion and its associated velocity. Atari Basic is too slow so it can not be read with atari basic. Faster langauges such ACTION and Assembly can read the velocity vectors directly from the joystick registers. (mention something about which bits represent the direction and speed.)
One thing the Atari Trak Ball lacks is a separate button that can function as the left mouse button. Since the mouse and the Track-ball are virtually the same device it should be possible to read and ST mouse using the Trak-ball read code. The 8-bits can read the ST left mouse if a pull-up resistor is added to pin 6.

Heres the pinout on the ST mouse.

```
_____________
\ 1 2 3 4 5 /
\ 6 7 8 9 /
---------
```

1- up/xb
2- down/xa
3- left/ya
4- right/yb
5- not connected
6- Fire/left mouse button
7- +5vdc
8- ground
9- Joystick 1 Fire/Right Mouse button.

I have included 3 programs that demostrate the trak-balls ability to read direction and velocity. One program is written in basic with a short assemble used to read the T-ball input vector. The other 2 programs are written in ACTION!

>>box !

The 16/32 alternatives to the our 8-bit machines don't happen to be the one
you suggest. The Amiga Is being produced by Commodore(Yuk) and they have
corrupted the machine. The a1000 a500 and a2000 are all very different
machines. Each one has plus and minus features, but are the plus features
enough to stimulate the atari 800/xe/xl comunity to buy one? The Amiga
is diffinitly not targeted for the general user,tho the A2000 has potential
in this realm. The Amiga is most useful to broadcast educators, since
it Audio and Video Capabilities make it well suit for that job. HAVE you
Seen the Job amigas do for MAX HEADROOM.

I have almost learned just about all one could know about the atari 8-bit
family, now it's really very useful to me. It would take me about 2 years
to learn the amiga inside and out by that time the next generation micros
will be arriving. My 800xl can do just about everything i need a computer
for now.

>>BTW I have worked for Atari (pre JT), Commodore (during the JT reign), and
>>Amiga (1984-5). Am I jaded ? YES I will not purchase a JT product ever
>>again !
ARE one of the Guys that the new commodore Dropped/Fired/layed off?
How long do we have before you start working on a new Machine in the
32 bit flavor?
Do you have ideas on what Jay Minor is up lately?

William M. Buford

>--

I didn't know there was a 400/800 version of Turbo BASIC.
The reason it only runs on the XL/XE series is it
hides like 11K of itself under the OS. This isn't
possible with a 400/800. Sure you could just have it sit in main memory
but your programming space would be like 18K instead of the
usual 29K.

2 cents worth.
Tom

636. Telephone Touch-Tone Program

Newsgroup: comp.sys.atari.8bit
Date: 1987-10-17 20:03:30 UTC
From: USEREK5X@mts.rpi.EDU
Message-ID: <791764@RPITSMTS.BITNET>
Source record: 117490

I am looking for a Touch-Tone dialing program for the 8-bit Atari that was published in some magazine a few years ago (between 1980 and 1984). I believe it was in Compute; Analog and Antic are two other (less likely) possibilities. If anyone has a program that will dial Touch-Tone frequencies from BASIC or knows where I can find the program in whatever magazine, I'd appreciate a response. Thanks in advance,

Bryant Line USEREK5X@RPITSMTS
BCL@RPITSMTS

Yes, a 400/800 version of Turbo BASIC does exist. If you or anyone
else can't find it on the net, it's available via the JACG disk
library. For more info, call the JACG BBS, number's listed below.

Such a program appeared recently on CompuServe. Also, the commercial
program "HomeCard," written by Russ Wetmore & sold through Antic,
can produce such tones.

Subject: Track-Ball Code! Basic And ACTION! ex.
To: info-atari8@score.stanford.edu
X-Original-To: info-atari8@score.stanford.edu

Taming your machine with a mouse has long been a dream of the ATARI 8-bitters.
The mouse had it's origins around the 1960's, but did see much use until the
1980's when the Mac,ST and Amiga were unveiled. The mouse was also used by the
engineering world as an input device for graphics workstations in the late
70's. The Track-ball is a close relative to the Mouse. A track-ball is
basicly the same device flipped over allowing the hand position the ball
directly.

The Old ATARI did have some foresight in developing input devices for the 8-bit
machines. The TrackBall is one of them. The Track-ball allows smooth tracking
of 2 dimensional motion and its associated velocity. Atari Basic is too slow
so it can not be read with atari basic. Faster langauges such ACTION and
Assembly can read the velocity vectors directly from the joystick registers.

(mention something about which bits represent the direction and speed.)
One thing the Atari Trak Ball lacks is a separate button that can function as the left mouse button. Since the mouse and the Track-ball are virtually the same device it should be possible to read and ST mouse using the Trak-ball read code. The 8-bits can read the ST left mouse if a pull-up resistor is added to pin 6.

Heres the pinout on the ST mouse.

```
-------------
\ 1 2 3 4 5 /
\ 6 7 8 9 /
---------
```

1- up/xb
2- down/xa
3- left/ya
4- right/yb
5- not connected
6- Fire/left mouse button
7- +5vdc
8- ground
9- Joystick 1 Fire/Right Mouse button.

I have included 3 programs that demostrate the trak-balls ability to read direction and velocity. One program is written in basic with a short assemble used to read the T-ball input vector. The other 2 programs are written in ACTION!

I didn't know there was a 400/800 version of Turbo BASIC.
The reason it only runs on the XL/XE series is it
hides like 11K of itself under the OS. This isn't
possible with a 400/800. Sure you could just have it sit in main memory
but your programming space would be like 18K instead of the
usual 29K.

2 cents worth.

Mail-From: G.ABRAMS created at 17-Oct-87 06:46:41
Date: Sat 17 Oct 87 06:46:41-PDT
From: Info-Atari Moderator <G.ABRAMS@Score.Stanford.EDU>
Subject: Volunteers needed
To: info-atari8@Score.Stanford.EDU, info-atari16@Score.Stanford.EDU

The incoming mailbox at Score overflowed recently because no one
loged in as moderator. I assume we all had good reasons. It appears
time to solicit new volunteers.

To assist as a moderator you need to be able to log into
Score.Stanford.Edu. That means you have to be able to make a telnet
connection on Arpanet. I have a set of instructions for moderators,
but basicly the work is to read the incoming mail, add people to the lists
upon request, and delete them either upon request or rejected mail.

We also need volunteers to help with the 8-bit program library on
bitnet. The volunteer should be on bitnet and be willing to
review existing programs and put them into a LISTSERV library. The
previous volunter had to drop out because of the load of schoolwork.
This effort will also require someone on ARPANET who can FTP the files
from an archive machine at Stanform and mail them to the librarian on
bitnet.

Please send your messages volunteering to abrams@mitre.arpa.
.

Acting as moderator should take an hour per week, Acting as
librarian can take many more hours.

Those service now are volunteers; additional help would certainly
be appreciated.

From: USEREK5X%mts.rpi.edu@itsgw.rpi.edu
Subject: Telephone Touch-Tone Program
To: Info-Atari8@score.stanford.edu

I am looking for a Touch-Tone dialing program for the 8-bit Atari
that was published in some magazine a few years ago (between 1980
and 1984). I believe it was in Compute; Analog and Antic are two
other (less likely) possibilities. If anyone has a program that
will dial Touch-Tone frequencies from BASIC or knows where I can
find the program in whatever magazine, I'd appreciate a response.
Thanks in advance,

Bryant Line USEREK5X@RPITSMTS

Yes, a 400/800 version of Turbo BASIC does exist. If you or anyone
else can't find it on the net, it's available via the JACG disk
library. For more info, call the JACG BBS, number's listed below.

Such a program appeared recently on CompuServe. Also, the commercial
program "HomeCard," written by Russ Wetmore & sold through Antic,

can produce such tones.

>>I of course am talking about the Amiga 1000. I bought my Atari 800 for
>>its great graphics, sound, and FRIENDLY user interface, BTW its SN is
>>00232 ! The Amiga 1000 IS the NEXT generation Atari 800 ! The chief
>>H/W architect for the Atari 2600, Atari 800 and the Amiga 1000 is Jay
>>Miner ! The Amiga's great MULTITASKING OS is just a super bonus to an
```

>>already super computer. BTW my Amiga's SN is D605 - its a preproduction
>>box !

The 16/32 alternatives to the our 8-bit machines don't happen to be the one
you suggest. The Amiga Is being produced by Commodore(Yuk) and they have
corrupted the machine. The a1000 a500 and a2000 are all very different
machines. Each one has plus and minus features, but are the plus features
enough to stimulate the atari 800/xe/xl comunity to buy one? The Amiga
is diffinitly not targeted for the general user,tho the A2000 has potential
in this realm. The Amiga is most useful to broadcast educators, since
it Audio and Video Capabilities make it well suit for that job. HAVE you
Seen the Job amigas do for MAX HEADROOM.

I have almost learned just about all one could know about the atari 8-bit
family, now it's really very useful to me. It would take me about 2 years
to learn the amiga inside and out by that time the next generation micros
will be arriving. My 800xl can do just about everything i need a computer
for now.

>>BTW I have worked for Atari (pre JT), Commodore (during the JT reign), and
>>Amiga (1984-5). Am I jaded ? YES I will not purchase a JT product ever
>>again !
ARE one of the Guys that the new commodore Dropped/Fired/layed off?
How long do we have before you start working on a new Machine in the
32 bit flavor?
Do you have ideas on what Jay Minor is up lately?

William M. Buford
DFlint02@ulkyvx.bitnet

Date: Fri, 16 Oct 87 10:00 EDT
From: <DFLINT02%ULKYVX.BITNET@forsythe.stanford.edu>
Subject: Track-Ball Code! Basic And ACTION! ex.
To: info-atari8@score.stanford.edu
X-Original-To: info-atari8@score.stanford.edu

Taming your machine with a mouse has long been a dream of the ATARI 8-bitters.
The mouse had it's origins around the 1960's, but did see much use until the
1980's when the Mac,ST and Amiga were unveiled. The mouse was also used by the
engineering world as an input device for graphics workstations in the late
70's. The Track-ball is a close relative to the Mouse. A track-ball is
basicly the same device flipped over allowing the hand position the ball
directly.

The Old ATARI did have some foresight in developing input devices for the 8-bit
machines. The TrackBall is one of them. The Track-ball allows smooth tracking
of 2 dimensional motion and its associated velocity. Atari Basic is too slow
so it can not be read with atari basic. Faster langauges such ACTION and
Assembly can read the velocity vectors directly from the joystick registers.

(mention something about which bits represent the direction and speed.)
One thing the Atari Trak Ball lacks is a separate button that can function as the left mouse button. Since the mouse and the Track-ball are virtually the same device it should be possible to read and ST mouse using the Trak-ball read code. The 8-bits can read the ST left mouse if a pull-up resistor is added to pin 6.

Heres the pinout on the ST mouse.

```
_____________
\ 1 2 3 4 5 /
\ 6 7 8 9 /
---------
```

1- up/xb
2- down/xa
3- left/ya
4- right/yb
5- not connected
6- Fire/left mouse button
7- +5vdc
8- ground
9- Joystick 1 Fire/Right Mouse button.

I have included 3 programs that demostrate the trak-balls ability to read direction and velocity. One program is written in basic with a short assemble used to read the T-ball input vector. The other 2 programs are written in ACTION!

I didn't know there was a 400/800 version of Turbo BASIC.
The reason it only runs on the XL/XE series is it
hides like 11K of itself under the OS. This isn't
possible with a 400/800. Sure you could just have it sit in main memory
but your programming space would be like 18K instead of the
usual 29K.

2 cents worth.

Mail-From: G.ABRAMS created at 17-Oct-87 06:46:41
Date: Sat 17 Oct 87 06:46:41-PDT
From: Info-Atari Moderator <G.ABRAMS@Score.Stanford.EDU>
Subject: Volunteers needed
To: info-atari8@Score.Stanford.EDU, info-atari16@Score.Stanford.EDU

The incoming mailbox at Score overflowed recently because no one
loged in as moderator. I assume we all had good reasons. It appears
time to solicit new volunteers.

To assist as a moderator you need to be able to log into
Score.Stanford.Edu. That means you have to be able to make a telnet
connection on Arpanet. I have a set of instructions for moderators,
but basicly the work is to read the incoming mail, add people to the lists
upon request, and delete them either upon request or rejected mail.

We also need volunteers to help with the 8-bit program library on
bitnet. The volunteer should be on bitnet and be willing to
review existing programs and put them into a LISTSERV library. The
previous volunter had to drop out because of the load of schoolwork.
This effort will also require someone on ARPANET who can FTP the files
from an archive machine at Stanform and mail them to the librarian on
bitnet.

Please send your messages volunteering to abrams@mitre.arpa.
.

Acting as moderator should take an hour per week, Acting as
librarian can take many more hours.

Those service now are volunteers; additional help would certainly
be appreciated.

From: USEREK5X%mts.rpi.edu@itsgw.rpi.edu
Subject: Telephone Touch-Tone Program
To: Info-Atari8@score.stanford.edu

I am looking for a Touch-Tone dialing program for the 8-bit Atari
that was published in some magazine a few years ago (between 1980
and 1984). I believe it was in Compute; Analog and Antic are two
other (less likely) possibilities. If anyone has a program that
will dial Touch-Tone frequencies from BASIC or knows where I can
find the program in whatever magazine, I'd appreciate a response.
Thanks in advance,

Bryant Line USEREK5X@RPITSMTS

Yes, a 400/800 version of Turbo BASIC does exist. If you or anyone
else can't find it on the net, it's available via the JACG disk
library. For more info, call the JACG BBS, number's listed below.

Such a program appeared recently on CompuServe. Also, the commercial
program "HomeCard," written by Russ Wetmore & sold through Antic,

can produce such tones.

>>one of idenity -- they fail to see what has been placed in front of their
>>faces.
>>I of course am talking about the Amiga 1000. I bought my Atari 800 for
>>its great graphics, sound, and FRIENDLY user interface, BTW its SN is
>>00232 ! The Amiga 1000 IS the NEXT generation Atari 800 ! The chief
>>H/W architect for the Atari 2600, Atari 800 and the Amiga 1000 is Jay
>>Miner ! The Amiga's great MULTITASKING OS is just a super bonus to an
```

>>already super computer. BTW my Amiga's SN is D605 - its a preproduction
>>box !

The 16/32 alternatives to the our 8-bit machines don't happen to be the one
you suggest. The Amiga Is being produced by Commodore(Yuk) and they have
corrupted the machine. The a1000 a500 and a2000 are all very different
machines. Each one has plus and minus features, but are the plus features
enough to stimulate the atari 800/xe/xl comunity to buy one? The Amiga
is diffinitly not targeted for the general user,tho the A2000 has potential
in this realm. The Amiga is most useful to broadcast educators, since
it Audio and Video Capabilities make it well suit for that job. HAVE you
Seen the Job amigas do for MAX HEADROOM.

I have almost learned just about all one could know about the atari 8-bit
family, now it's really very useful to me. It would take me about 2 years
to learn the amiga inside and out by that time the next generation micros
will be arriving. My 800xl can do just about everything i need a computer
for now.

>>BTW I have worked for Atari (pre JT), Commodore (during the JT reign), and
>>Amiga (1984-5). Am I jaded ? YES I will not purchase a JT product ever
>>again !
ARE one of the Guys that the new commodore Dropped/Fired/layed off?
How long do we have before you start working on a new Machine in the
32 bit flavor?
Do you have ideas on what Jay Minor is up lately?

William M. Buford
DFlint02@ulkyvx.bitnet

From: <DFLINT02%ULKYVX.BITNET@forsythe.stanford.edu>
Subject: Track-Ball Code! Basic And ACTION! ex.
To: info-atari8@score.stanford.edu
X-Original-To: info-atari8@score.stanford.edu

Taming your machine with a mouse has long been a dream of the ATARI 8-bitters.
The mouse had it's origins around the 1960's, but did see much use until the
1980's when the Mac,ST and Amiga were unveiled. The mouse was also used by the
engineering world as an input device for graphics workstations in the late
70's. The Track-ball is a close relative to the Mouse. A track-ball is
basicly the same device flipped over allowing the hand position the ball
directly.

The Old ATARI did have some foresight in developing input devices for the 8-bit
machines. The TrackBall is one of them. The Track-ball allows smooth tracking
of 2 dimensional motion and its associated velocity. Atari Basic is too slow
so it can not be read with atari basic. Faster langauges such ACTION and
Assembly can read the velocity vectors directly from the joystick registers.

(mention something about which bits represent the direction and speed.)
One thing the Atari Trak Ball lacks is a separate button that can function as the left mouse button. Since the mouse and the Track-ball are virtually the same device it should be possible to read and ST mouse using the Trak-ball read code. The 8-bits can read the ST left mouse if a pull-up resistor is added to pin 6.

Heres the pinout on the ST mouse.

```
_____________
\ 1 2 3 4 5 /
\ 6 7 8 9 /
---------
```

1- up/xb
2- down/xa
3- left/ya
4- right/yb
5- not connected
6- Fire/left mouse button
7- +5vdc
8- ground
9- Joystick 1 Fire/Right Mouse button.

I have included 3 programs that demostrate the trak-balls ability to read direction and velocity. One program is written in basic with a short assemble used to read the T-ball input vector. The other 2 programs are written in ACTION!

I didn't know there was a 400/800 version of Turbo BASIC.
The reason it only runs on the XL/XE series is it
hides like 11K of itself under the OS. This isn't
possible with a 400/800. Sure you could just have it sit in main memory
but your programming space would be like 18K instead of the
usual 29K.

2 cents worth.

Mail-From: G.ABRAMS created at 17-Oct-87 06:46:41
Date: Sat 17 Oct 87 06:46:41-PDT
From: Info-Atari Moderator <G.ABRAMS@Score.Stanford.EDU>
Subject: Volunteers needed
To: info-atari8@Score.Stanford.EDU, info-atari16@Score.Stanford.EDU

The incoming mailbox at Score overflowed recently because no one
loged in as moderator. I assume we all had good reasons. It appears
time to solicit new volunteers.

To assist as a moderator you need to be able to log into
Score.Stanford.Edu. That means you have to be able to make a telnet
connection on Arpanet. I have a set of instructions for moderators,
but basicly the work is to read the incoming mail, add people to the lists
upon request, and delete them either upon request or rejected mail.

We also need volunteers to help with the 8-bit program library on
bitnet. The volunteer should be on bitnet and be willing to
review existing programs and put them into a LISTSERV library. The
previous volunter had to drop out because of the load of schoolwork.
This effort will also require someone on ARPANET who can FTP the files
from an archive machine at Stanform and mail them to the librarian on
bitnet.

Please send your messages volunteering to abrams@mitre.arpa.
.

Acting as moderator should take an hour per week, Acting as
librarian can take many more hours.

Those service now are volunteers; additional help would certainly
be appreciated.

From: USEREK5X%mts.rpi.edu@itsgw.rpi.edu
Subject: Telephone Touch-Tone Program
To: Info-Atari8@score.stanford.edu

I am looking for a Touch-Tone dialing program for the 8-bit Atari
that was published in some magazine a few years ago (between 1980
and 1984). I believe it was in Compute; Analog and Antic are two
other (less likely) possibilities. If anyone has a program that
will dial Touch-Tone frequencies from BASIC or knows where I can
find the program in whatever magazine, I'd appreciate a response.
Thanks in advance,

Bryant Line USEREK5X@RPITSMTS

Yes, a 400/800 version of Turbo BASIC does exist. If you or anyone
else can't find it on the net, it's available via the JACG disk
library. For more info, call the JACG BBS, number's listed below.

Such a program appeared recently on CompuServe. Also, the commercial
program "HomeCard," written by Russ Wetmore & sold through Antic,

can produce such tones.

To; The administrator of the Atari8 Digest

I can not print the Digest.

Why is the digest protected.

Is there a way to undo this protection so I can print it?

Thank You.

Mike

>>its great graphics, sound, and FRIENDLY user interface, BTW its SN is
>>00232 ! The Amiga 1000 IS the NEXT generation Atari 800 ! The chief
>>H/W architect for the Atari 2600, Atari 800 and the Amiga 1000 is Jay
>>Miner ! The Amiga's great MULTITASKING OS is just a super bonus to an
```

>>already super computer. BTW my Amiga's SN is D605 - its a preproduction
>>box !

The 16/32 alternatives to the our 8-bit machines don't happen to be the one
you suggest. The Amiga Is being produced by Commodore(Yuk) and they have
corrupted the machine. The a1000 a500 and a2000 are all very different
machines. Each one has plus and minus features, but are the plus features
enough to stimulate the atari 800/xe/xl comunity to buy one? The Amiga
is diffinitly not targeted for the general user,tho the A2000 has potential
in this realm. The Amiga is most useful to broadcast educators, since
it Audio and Video Capabilities make it well suit for that job. HAVE you
Seen the Job amigas do for MAX HEADROOM.

I have almost learned just about all one could know about the atari 8-bit
family, now it's really very useful to me. It would take me about 2 years
to learn the amiga inside and out by that time the next generation micros
will be arriving. My 800xl can do just about everything i need a computer
for now.

>>BTW I have worked for Atari (pre JT), Commodore (during the JT reign), and
>>Amiga (1984-5). Am I jaded ? YES I will not purchase a JT product ever
>>again !
ARE one of the Guys that the new commodore Dropped/Fired/layed off?
How long do we have before you start working on a new Machine in the
32 bit flavor?
Do you have ideas on what Jay Minor is up lately?

William M. Buford
DFlint02@ulkyvx.bitnet
(I will buy no 16/32 bit before its time!)
(Unless it has about 4Meg ram!)

Subject: Track-Ball Code! Basic And ACTION! ex.
To: info-atari8@score.stanford.edu
X-Original-To: info-atari8@score.stanford.edu

Taming your machine with a mouse has long been a dream of the ATARI 8-bitters.
The mouse had it's origins around the 1960's, but did see much use until the
1980's when the Mac,ST and Amiga were unveiled. The mouse was also used by the
engineering world as an input device for graphics workstations in the late
70's. The Track-ball is a close relative to the Mouse. A track-ball is
basicly the same device flipped over allowing the hand position the ball
directly.

The Old ATARI did have some foresight in developing input devices for the 8-bit
machines. The TrackBall is one of them. The Track-ball allows smooth tracking
of 2 dimensional motion and its associated velocity. Atari Basic is too slow
so it can not be read with atari basic. Faster langauges such ACTION and
Assembly can read the velocity vectors directly from the joystick registers.

(mention something about which bits represent the direction and speed.)
One thing the Atari Trak Ball lacks is a separate button that can function as the left mouse button. Since the mouse and the Track-ball are virtually the same device it should be possible to read and ST mouse using the Trak-ball read code. The 8-bits can read the ST left mouse if a pull-up resistor is added to pin 6.

Heres the pinout on the ST mouse.

```
-------------
\ 1 2 3 4 5 /
\ 6 7 8 9 /
---------
```

1- up/xb
2- down/xa
3- left/ya
4- right/yb
5- not connected
6- Fire/left mouse button
7- +5vdc
8- ground
9- Joystick 1 Fire/Right Mouse button.

I have included 3 programs that demostrate the trak-balls ability to read direction and velocity. One program is written in basic with a short assemble used to read the T-ball input vector. The other 2 programs are written in ACTION!

I didn't know there was a 400/800 version of Turbo BASIC.
The reason it only runs on the XL/XE series is it
hides like 11K of itself under the OS. This isn't
possible with a 400/800. Sure you could just have it sit in main memory
but your programming space would be like 18K instead of the
usual 29K.

2 cents worth.

Mail-From: G.ABRAMS created at 17-Oct-87 06:46:41
Date: Sat 17 Oct 87 06:46:41-PDT
From: Info-Atari Moderator <G.ABRAMS@Score.Stanford.EDU>
Subject: Volunteers needed
To: info-atari8@Score.Stanford.EDU, info-atari16@Score.Stanford.EDU

The incoming mailbox at Score overflowed recently because no one
loged in as moderator. I assume we all had good reasons. It appears
time to solicit new volunteers.

To assist as a moderator you need to be able to log into
Score.Stanford.Edu. That means you have to be able to make a telnet
connection on Arpanet. I have a set of instructions for moderators,
but basicly the work is to read the incoming mail, add people to the lists
upon request, and delete them either upon request or rejected mail.

We also need volunteers to help with the 8-bit program library on
bitnet. The volunteer should be on bitnet and be willing to
review existing programs and put them into a LISTSERV library. The
previous volunter had to drop out because of the load of schoolwork.
This effort will also require someone on ARPANET who can FTP the files
from an archive machine at Stanform and mail them to the librarian on
bitnet.

Please send your messages volunteering to abrams@mitre.arpa.
.

Acting as moderator should take an hour per week, Acting as
librarian can take many more hours.

Those service now are volunteers; additional help would certainly
be appreciated.

From: USEREK5X%mts.rpi.edu@itsgw.rpi.edu
Subject: Telephone Touch-Tone Program
To: Info-Atari8@score.stanford.edu

I am looking for a Touch-Tone dialing program for the 8-bit Atari
that was published in some magazine a few years ago (between 1980
and 1984). I believe it was in Compute; Analog and Antic are two
other (less likely) possibilities. If anyone has a program that
will dial Touch-Tone frequencies from BASIC or knows where I can
find the program in whatever magazine, I'd appreciate a response.
Thanks in advance,

Yes, a 400/800 version of Turbo BASIC does exist. If you or anyone
else can't find it on the net, it's available via the JACG disk
library. For more info, call the JACG BBS, number's listed below.

Such a program appeared recently on CompuServe. Also, the commercial
program "HomeCard," written by Russ Wetmore & sold through Antic,

can produce such tones.

644. Re: 400/800 Turbo BASIC (FROST BASIC)

Newsgroup: comp.sys.atari.8bit
Date: 1987-10-20 21:03:46 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8710202103.AA04253@mitre-bedford.ARPA>
Source record: 117498

Yes, there is a 400/800 Turbo BASIC, which does not hide under the ROM
as the XL/XE version does. This makes it suitable for use with even those
DOS versions which use this space. The XL/XE version, I am told, DOES
work with DOS-XL, even though that program uses the RAM under ROM too.
(This according to John Dunning.)

If anyone needs either program, I have them and can mail them or post them
to the net, though it may take a few days to get everything online.

-John Sangster, jhs@mitre-bedford.arpa

645. Kermit-65 Repost, part 1/3

Newsgroup: comp.sys.atari.8bit
Date: 1987-10-20 21:48:00 UTC
From: jrd@STONY-BROOK.SCRC.SYMBOLICS.COM
Message-ID: <19871020214812.3.JRD@GRACKLE.SCRC.Symbolics.COM>
Source record: 117499

```
This is a repost of Kermit-65, with bug-fixes and enhancements in
response to the feedback from the first release. The three parts are
the revised documentation, following this text, and binaries for
KERMIT.COM and KERMITNR.COM, exactly the way the first posting was done.
Please see the documentation for a description of the changes since
first release. (Yes, the infamous binary bug is fixed).

Archive maintainers: Please replace any old versions of Kermit-65 with
this one.

Here's the doc:
-------------------------------kermit.doc--------------------------------
Kermit-65 Manual and bug list Page 1

Kermit-65 for Atari 800s

By John Dunning. Bug reports to me (JRD@Symbolics.COM) via Arpanet.
Other net users will have to find some way of getting mail to Ar-
panet, then use the above address.

Kermit-65 is a port of the kermit-65 available for Commodore frobs.
It runs on 48K Atari 800 family machines. Current version (second
release) is 3.3.

Capabilities:

File transfer, text and binary:

Without going into excruciating detail here, Kermit-65 is a fairly
complete implementation of a user side, using the KERMIT protocol.
It's been tested against Kermit-11 under RSX, and C-Kermit under
VMS and Un*x, and seems to work fine. For a description of what
the KERMIT file protocol is all about, and something about how the
it works, see the 'Kermit protocol' section at the end of this do-
cument.

Terminal emulation:

Glass tty, Vt52, or Vt100. Supports 3 flavors of screen
configuration; Atari standard screen, 80-column pannable
(40-column visible) like VTERM, and 80-column graphics, like
V10SQR. Terminal emulation modes may be used in any combination
with screen configurations, though some combinations won't work
real well; for instance trying to do full-screen Vt100-style ed-
itting when using the Atari screen is a good way to lose.

Local file management:
```

Kermit-65 includes Directory, Erase, and Rename commands, allowing the user to do most kinds of maintainance operations without leaving the program. It also allows you set set the default drive to any value 1 thru 8, so you're not stuck using a single drive for everything.

Typing at Kermit-65:

The command processor accepts command lines, consisting of a keyword, optionally some more keywords, and optional values. Things in command lines are delimited by spaces, and terminated by <CR>. At any time, you may type '?' to get a list of valid completions for the word you're typing. You need not type keywords completely; however much uniquely identifies the word you want is enough. At any time, <ESC> will attempt to complete what you've

typed so far. Note that if you've typed a word, but haven't hit a <space> or <ESC> yet, so that the cursor's at the end of the word, '?' will tell you that there's only the one possibility. Hit a space, then '?', for a list of possibilities for the next word. Some commands are 'defaults' in the sense that if you type something non-unique, and hit escape, and one of the possibilities is a 'default', it will win over the other possibilities. One example of this is 'Send'.
Example: The following illustrates a typical interaction between you, the user, and Kermit-65. The stuff that Kermit types (prompts, echos of partial commands, and help) is on the left, stuff typed by the user is in the middle, and commentary is on the right.

Kermit types: You type: Comments:

"Kermit-65>" Kermit prompts.

"s?" User starts typing a
command starting with
"s", then hits "?" for
help.

"Keyword, one of the following: Kermit prints possible
set show for "s"...
send
Kermit-65>s" and reprompts, with the
partial command.

"et?" User finishes the "set"
command, and asks for
help again.

"Keyword, one of the following: Kermit prints the (one)
set possible completion.
Kermit-65>set"

" ?" User hits a space, then
asks for help again.

"Keyword, one of the following:" Kermit prints possible
(various subcommands of 'set' here) completions for words
that can follow "set"

Kermit-65 Manual and bug list Page 3

Kermit-65 commands:

Bye
Tells the kermit on the other side to log out, and ex-
its Kermit-65.

Finish
Tells the kermit on the other side to exit server
mode, but stay logged in.

Connect
Puts Kermit-65 in terminal mode, using whatever param-
eters are currently set for Terminal and Screen confi-
guration. See 'Set Terminal' and 'Set screen' for
more details.

Quit
Exit from Kermit-65 back to Atari DOS.

Exit
Same as Quit.

Get
<file spec>
Ask the kermit on the other side to send the named
file, using whatever file and protocol parameters are
currently in effect. See 'Set' for more details.
Note that <file spec> may be wildcarded; assuming the
serving kermit allows that. In that case the serving
kermit may send several files; Kermit-65 will try to
receive all of them.

Send
<file spec>
Send the named file to the kermit on the other side.
If the file spec is wildcarded (using DOS FMS wildcard
rules) all matching files are sent. In the latter
case, the Kermit on the other side should be in Server
mode, so that it can deal with a whole sequence of in-
coming files.

Receive
<file name>
Attempt to receive into the named file. Assumes the
other kermit is already trying to send it. If no file
name is given, Kermit-65 will attempt to get the name

from the file-header information coming from the other side. This is the command to use after telling the other kermit "Send <something>".

Kermit-65 Manual and bug list Page 4

Set
Baud
(50..9600)
Sets baud rate on the comm port to the supplied value.

Parity
Even, Odd, Mark, Space, None
Sets specified parity for the comm port. See the Atari 850 man for more details on the behaviour of the various parity options.

Word-size
Seven, Eight
Set frame size used for comm port. The default is eight-bit. The preferred value for this depends on what the parameters of the serial line are set to on the other side. In my experience, older systems will tend to use seven-bit configurations, more modern ones will tend to use eight-bits. If you're not sure, it usually works to use eight-bit.

Default-disk
<1..8>
Sets the default disk for all file operations. Legal values are 1 to 8, inclusive.

Rs232-registers
<16-bit hex number>
Directly sets some of the the values used when configuring the serial port. Specifically, the high byte is used as the AUX1 parameter for the XIO 38 (configure translation and parity) and the low byte is used as the AUX1 parameter for the XIO 36 (configure baud rate and word size). This allows settings to be used that aren't covered by the supplied keywords in Baud, Parity, and Word-size.

Debugging
Off, Terse, Verbose
Turns on/off various debug msgs strewn around in the code.

Eight-bit-quoting
On, Off
Turns on/off eight-bit mode quoting in the kermit protocol. The default is off.

File-warning
On, Off
When this mode is on, Kermit-65 will refuse to overwrite files when receiving. When it attempts to receive a file that's already present, it will alter the filename of the incoming file so as not to overwrite the old version. The algorithm for altering the filename is to replace the extension field of the name with a 2 digit hex number, and retry. If the file still exists, the number is incremented. This repeats until a free name is found, or the extension reaches "FF", at which time the receive is aborted. (I think it's never possible to get that far anyway, as you can't put 256 files on one of these disks)

File-type
Atascii
This is a standard atari text file, and is the default mode. End of line is signalled by the ATEOL character ($9B). When sending, other ATASCII characters are translated to their ASCII equivalents, ie ATTAB ($7F) -> Tab ($09), ATRUB ($7E) -> Rubout ($7F). The file header info generated indicates that a text file is being sent. Receiving one does the opposite transformation.

Ascii
Files are sent/received as ordinary ascii-text. Line terminators are assumed to be CR ($0D) followed by LF ($0A), and are handled in the usual kermit fashion. No translation of data happens. This mode isn't the right thing for regular old text files, but is useful for sending around files that are output in plain ascii from various utilities. For example, I have a word processor program which produces formatted output files in ascii, intended to be dumped directly to a printer. This mode gets them over to my pdp-11's print spooler.

Binary
Data is sent in kermit binary form, no line terminators etc.

Flow-control
On, Off
Turns ^S^Q flow control on/off for the incoming line. See 'Com port handling', below, for more details.

Ibm-mode
On, Off
Turns on/off 'IBM mode'. This is apparently a standard thing in kermit implementations, made necessary by the wierditudes designed into the blue equipment. This code has been left as is, so it's got some chance of working, but has not been tested.

Local-echo
On, Off
Controls echo mode in terminal emulator. Default is off.

Send
End-of-line, Padding, Timeout, Pad-char, Quote-char, Eight-bit-quote, Packet-length
Sets one of the listed parameters for the transmitting side of the kermit protocol. Padding, timeout (seconds), and packet-length are in decimal, the others (character codes) are in hex. This command is primarily used when talking to a kermit that can't or won't use the standard set of protocol characters for beginning-of-frame, end-of-frame, etc. As such, it's not generally useful, at least I've never seen a kermit that required it. There are things that might come in handy, though. For instance, if you've got an exceptionally dirty phone connection, you might want to set the frame size down from the default of 94. In that case, you might say "Set Send Frame-size 30". Note that Send parameters can be reset by the other Kermit sending one of the kinds of packets that request certain values, so you may have to tell him directly, to get the effect you want.

Receive
All parameters settable same as 'Send'

Screen-driver
Atari
The standard 24x40 Atari screen driver. This mode does its output to the internal E: device. This isn't very useful for complicated things, but is supplied in case kermit's running someplace where there's not enough memory to do anything better. (Besides, I had to have all the code for it lying aound for other reasons, so why not?)

40-column
A 24x80 screen, using the character CTIA mode. Since that mode only allows 40 visible columns, the screen is pannable left to right, allowing any 40-column

chunk to be displayed. The terminal code will attempt to keep the cursor visible by panning around while output is happening. You can also pan manually using the Start and Select keys. In this mode, reverse- video output works, but none of the other highlighting types.

80-column
A 24x80 screen, using the hi-res (320 bits/raster) graphics CTIA mode. In this mode, both reverse video and underlining are supported. This is the default setting for screen mode.

Terminal-emulation
Vt100, Vt52, None
Sets the terminal emulation mode to the specified value. The default is Vt100.

Show
any of the same keywords as 'Set', or 'All'
Display the value(s) of the specified thing(s). 'All' displays the values of everything in sight.

Status
Dump various goodies about the last file transfer; characters in, out, naks, timeouts etc.

Directory [<filespec>]
Display a directory list from the default drive. <filespec> is optional, if omitted, it defaults to "*.*".

Rename <from-filespec> <to-filespec>
Does a rename operation on files on the default drive. Either filespec may be wildcarded, in which case the rename operation happens according to the rules described in the ATARI OS FMS documentation.

Erase <filespec>
Erases files on the default drive. Filespec may be wildcarded, in which case the erase operation happens according to the rules described in the ATARI OS FMS documentation.

Save
Dump Kermit-65 parameters such as screen settings, send/receive parameters, etc to an init file "KERMIT.INI" on the default disk.

Restore
Read parameters from "KERMIT.INI" back into the running Kermit-65.

Help
Gives a summary of the above command list.

Other interesting things about terminal modes:

Depending on what terminal you're using, there are several things which may be of interest. In 40 or 80 column modes, there's a status line under the 24 data lines. It displays what special keys are active, and the status of the comm port. In 40 column mode, Start pans the screen right, and Select pans left. In both 40 and 80 col modes, Option is used to get the kermit's attention. In Atari mode, c-Y is used instead.
Once you have kermit's attention, it wants a character; one of:

C Break the connection
B Send a break (approx 1/4 sec)
S Display status

Function keys:

Kermit-65 can generate function key sequences ala VT100. The current function key bindings are as follows: (c-sh- means control-shift...)
c-sh-0..c-sh-9 keypad 0 thru 9
c-sh-. keypad dot
c-sh-backspace keypad minus
c-sh-, keypad comma
c-sh-return Enter
c-sh-q..c-sh-r PF1..PF4
c-sh-- Up arrow
c-sh-= Down arrow
c-sh-< Left arrow
c-sh-> Right arrow

Other key bindings for things not on the Atari keyboard:
sh-< { (left brace)
sh-> } (right brace)
sh-backspace ~ (tilde)
c-sh-backspace, or c-7 ` (backquote)

These key bindings aren't quite what I had in mind, but the OS rom won't let me get at all the control-shift keypresses, so they'll have to do for now. I encourage any feedback about how these feel. I've been using them for a while now, and they don't seem as bad as I expected. In particular, they work passably well when using EDT (I'm typing this document with it), which I think is an indication that they're useable, as it's a real keypad hog.

Other special keys:

The Atari key (/|\ on 800 vintage dinosaurs like mine, |/| on newer 800XL vintage equipment) behaves in a special fashion when

using Kermit-65. It toggles a flag that causes input from the comm port to be held up, rather than processed as soon as possible. This is useful for causing the screen to hold up temporarily when in terminal mode. If flow control is enabled, it behaves in the expected fashion; it'll tell the other side to shut up until you press the Atari key again, to let pending input be processed again.

The status line:

When in 40-column or 80-column terminal modes, there's a 25th line below the usual 24 lines of terminal screen. This is the status line. It will look something like this:

K65: Option + o v Rs ok

There are several interesting things displayed here: At the left side, after "K65", is a list of which special keys (option, select, start) are active at the moment. If you press Option, this will change to a prompt for the special characters that can follow Option. In column 22 ('+', above) will appear '+' or '-', or space. This indicator shows you the state of the flow-control logic; + means incoming traffic is enabled, - means it's disabled. Note that it when flow-control is turned on (see commands, above) this flag will toggle back and forth between + and - as the flow-control logic does its thing. If flow-control is turned off, it will just sit on + all the time. Column 24 ('o' above) will contain a blot if comm-port reading is suspended, space otherwise. In column 26, ('v') above, is the caps lock indicator. It will display an up-arrow if caps are locked, or a down-arrow if not. In column 32 is a message describing the last known state of the comm port.

Com port handling:

In its current configuration, Kermit-65 expects to talk thru an Atari 850. In principal, that ought not to be a restriction, but I (JRD) only have an 850 to test with, and don't know what requirements there are for other devices. I've tried to be scrupulous about sticking to the documented interfaces to things, however, so I'd expect any driver that adheres to the spec to work.

The port's opened and closed a lot; you'll hear it, as I've left the 'noisy bus' option turned on. It uses page 6 ($600) as an IO buffer. Since that's only 256 bytes, there's the possibility of overruns at high baud rates. When flow-control's on, Kermit will attempt to shut off the other side when it sees more than 50 bytes pending; it will turn it back on when there's less than 10.

As of this writing, Kermit-65 has been out in the field for a while, and seems to work ok with things other than 850s. One word of caution; I've gotten some feedback to the effect that the default timeout values I chose are too short for reliable operation at low baud rates. I've decided not to change the defaults, as you can easily change them in your KERMIT.INI file, and because most folks seem to have access to 1200 bps modems and things these days. However, if you're running at 300 bps and seeing reliability problems, try pushing the timeouts up to say 15 sec or so.

Other ramblings:

Version 3.3 loads at $2D20, and uses up thru about $B000. That means it'll only run on 48K machines. It appears to run fine on XL and XE equipment, but most of my testing has been on an 800, so there may be some problems. BTW, that load address was chosen because the latest version of DOS XL for Indus GT's uses up thru $2D14 when it's configured for two drives, and the 850 driver is loaded. Older versions of DOS XL take up less memory, as does DOS. I don't know what the requirements are for things like Spartados. If anyone comes up with a conflict, let me know, and I'll assemble you a version that's org'ed somewhere else.

On XLs and XEs, kermit-65 will require that the machine be booted with BASIC disabled, as it's not yet bright enough to detect that that's where it is and map out the cart. (if anyone knows how to do that, and feels like saving me some work...) Kermit-65 is available in 'bare' form, or with an autoloader for the 850 driver prepended to it. The bare version requires that you load whatever rs232 driver you're going to use first, then run kermit. The autoloader equipped version does that for you.

Kermit-65 Manual and bug list Page 11

For those of you who have YAU (posted separately) the byte count and checksum values for KERMIT.COM and KERMITNR.COM respectively are 24622, #x5F17; and 24408, #x1560.

Kermit-65 Manual and bug list Page 12

Credits

I blew it when distributing the first version of this document, and forgot to include this section. Mea culpa.

Many thanks to my beta testers, in particular Marshall Abrams, for his patience in dealing with initial versions of this thing, and for aid in making this document clearer. Thanks also to John Sangster for helping nail down my obscure terminal emulator bugs, and miscellaneous kibutzing. (Sorry John, I still haven't gotten in the key defining util. Maybe next version).

Kermit-65 Manual and bug list Page 13

Bugs and misfeatures:

There's no way to set the comm port to other than R1:. Does anyone care?

The help processor doesn't deal properly with upper-case, and thinks there are no completions.

Vt100 mode is missing still missing insert/delete character.

Blinking fields, bright fields, double-high, double-wide, and 132-col mode are not supported. (Reverse vid and underline are)

There's currently no way to set the screen colors.

It's possible to confuse yourself by hitting c-1 in terminal mode, as my screen drivers ignore it, but Atari's doesn't. You're fine until you break the connection, then everything appears to wedge up.

Flow control for the incoming side of the connection isn't implemented. This can cause problems when trying to send at high baud rates to a host that's got a stupid serial driver, or a small typeahead buffer.

The part of the command parser that deals with pathnames is completely bankrupt (that's what I get for using old code), and doesn't work properly unless it's told that a null pathname is legal. The result of all this is that when entering pathnames and asking for help before entering any data, it will tell you "input file spec or confirm with <cr>". Pay no attention to the man behind the curtain; you really do have to put a pathname in there for anything to happen.

Kermit-65 Manual and bug list Page 14

Bugs fixed for v 3.1

Save and Restore now actually do something, instead of being effectively no-ops.

Rename and Erase commands are now implemented. This means that virtually all file operations one cares about (while up/downloading) can be done without leaving Kermit.

File-warning mode has been fixed so that it really does something useful, instead of just bitching about the file conflict.

The pathname parsing substrate has been installed, so that defaulting and merging can be done in a reasonable fashion, instead of by ad hoc kludgery.

The screen hacking code has been cleaned up a good bit, so as not to be continually clearing the screen when doing transfers.

Logging code has been added to tell the user what files are being sent and received.

Status and help commands in terminal mode are now working.

The directory command now takes an optional filespec parameter.

Bugs fixed for v 3.2

Binary mode now works again. (Sheesh!)

Rename and Erase routines now make sure the comm port's closed before attempting to hack the disk.

The user interface has been cleaned up some; all numeric values other than character codes and some debugging info is now displayed and entered in decimal, rather than hex.

Bugs fixed for v 3.3

Fixed a dumb bug in terminal code that caused graphics mode to be entered at unexpected times.

Fixed file reading code so as not to get confused and generate an extra byte when running under non-standard things like SpartaDos.

Cleaned up Directory code; using new pathname-mapping substrate.

Added support for wildcarded pathnames in Send code.

Fixed packet-dumping debug code to not mask off top bit of char, and quote everything to keep from interpreting screen hacking chars.

Fixed init code to look for an init file on D1, and read it if found.

Fixed flow control code so as not to wedge up unexpectedly.

Re-enabled the suspend-input capability, using the Atari (/|\) key.

Break (Option-B) in terminal mode has been fixed.

Cleaned up the font used in 80-col mode.

Removed Speedscript file type, as Speedscript apparently just uses plain vanilla text files. Changed default file type to Atascii.

Added caps lock functionality, similar to standard Atari kbd driver.

Fixed a bug in terminal mode that was trashing the stack.

The Kermit Protocol

The following a brief description of the Kermit file protocol, excerpted from one of the many documents kicking around. If you already know what it is, or don't care, skip this section.

The Kermit protocol allows many (if not most) types of computer systems to effect, at minimum, error free file transfer with other systems and microcomputers over asynchronous lines.

Introduction

With the widespread use of personal computers the need for file exchange between systems has become of foremost concern among users and managers alike. There are many commercial products available which meet this need, some of which may offer more advanced functions such as transparent record oriented file access. Networks that do this, such as DECnet, can be expensive, and if your computer or microcomputer is not on the network your needs won't be met. Transfer of files with removable disks can work, but generally only when the computers are of the same type, it's not very useful when the systems are removed in location. Rarely will a larger mini or supermini be able to read a microcomputer's disk.

A more realistic approach, from both cost and convenience, is to find a way to use ordinary telecommunications and/or in-house PBX systems to connect computers and microcomputers together. If a local connection using a PBX or front end switch is not available, there is always dialup access with standard 103/212 modems. Data can be transferred with very simple methods, such as TYPING a file on one system and capturing it on the other system, but this gives no protection from noise and overrun of data. It is not very user friendly either. What is really needed is a protocol to accomplish file transfer reliably and efficiently.

The first obvious use of any program or protocol designed to accomplish file transfer is to be able to provide the ability to support file uploads and downloads from minis and superminis such as the VAX and PDP-11 to remote personal computers, such as the Atari 800. It should also be widely available for many different micros and mainframes. File transfer from micro to micro, as well as from a larger central host, should be possible. The command interface should be easy to learn, and require no intervention from a central site operator or other user. The many implementations of Kermit follow these lines, and all versions allow some form of transfer in either direction. More advanced versions,

such as those found on the PDP-11, DEC10/20 and VAX, offer what is known as server operation, which allow the remote (connected) Kermit system to completely control the file exchanges from their system. Since as of this writing (October 9, 1985) there are available over 160 versions of Kermit available for numerous mi-

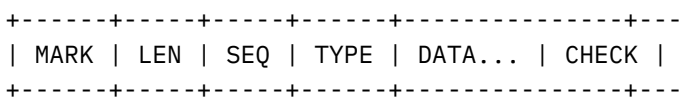
cro, mini and mainframe configurations, Kermit addresses this need quite well.

While the primary use of Kermit will likely be to support file transfer from microcomputer to mini/supermini and mainframe connections, there are many uses for Kermit for connections from mini to mini and so on.

The Kermit protocol

The Kermit protocol is designed to operate over normal asynchronous terminal lines. All data and commands are transferred with a packet oriented protocol, basically consisting of a start of packet character (normally SOH), followed by length, control, data and checksum fields. Communication is half duplex, in that for every packet sent, the sender must wait for either an acknowledgement packet (ACK) or a negative acknowledgement packet (NAK). Transmission is in ascii, with no requirements for the transmission of eight bit characters or control characters other than control-A for marking the start of a packet. All 'control' characters imbedded in the data are prefixed to convert them to printable characters, the same applying to eight bit characters if required by the characteristics of the line. Since there are many different implementations of Kermit, the protocol provides a mechanism by which the capabilities of two connected Kermits can be negotiated to allow for differences in the level of protocol support. Examples of protocol features that not all Kermits understand include data compression and transfer of file attributes.

The packet format is



where all fields consist of ASCII characters, and the char function converts a number in the range 0-94 (10) to a printable ASCII character by adding 32 (10). The MARK, LEN, SEQ and TYPE fields are one byte, the DATA field is variable in size, and the CHECK field is one to three bytes in size.
The MARK (normally control A) signifies the start of a packet. The length field tells how long the rest of the packet is. The SEQ field is used to insure synchronization used to detect lost or

duplicate packets. The SEQ number wraps around every 64 packets due to the need to encode it as a printable ascii character in the range 32 (10) to 126 (10). The TYPE field specifies whether the packet is a DATA or CONTROL packet. The DATA section is used for the actual transfer of data or informative messages from a Kermit server, this field can be up to 90 characters in length. Any character whose low seven bits fall in the range of 0 to 37 (8),

ie, char and 177 (8) is less than 40 (8), will have the value 100 (8) exclusive or'ed (xor'ed) with itself and be prefixed by a shift character, '#'. Other shift characters may be use for eight bit characters if the line characteristics require such. Data compression may also occur in the data field, this is done with yet another shift code and byte count sequence. The CHECK field is a checksum, either a one character, two character or three character CRC check; the sender computes it and the receiver must compute it and compare. A checksum mismatch will result in the receiver sending a NAK packet (negative acknowledgment) which directs the sender to resend the NAK'ed packet. The packet may be following by a terminator (likely an ascii 13). This terminator is NOT part of the protocol and is sent only to tell the receiver that a 'line' is present. Not all Kermit implementations require this; all Kermits will discard data outside of a packet in any event.

Error detection and recovery is by checksum, as noted, and by packet read timeouts. If the packet should be corrupted the checksum will be incorrect, the receiver will NAK the packet. If an expected packet never arrives within the timeout period, or if the received packet is not the expected one (as determined by the SEQ field) the packet will also be NAK'ed. There are limits as to how many times an expected packet will be NAK'ed without aborting the current operation.

Packet types

D Data
Y Acknowledgement (ACK), test may be in DATA field
N Negative Acknowledgement (NAK)
S Send initiate (Send-Init)
R Receive Initiate
B Break (EOT, end of transmission)
F File name header
Z End of file (EOF, end of current file)
E Error packet, text may be present in DATA field
G Generic SERVER command. The first character in the
data field will be a command to a server, arguments
may follow that character.
I Login, user and password follow in data field
C CWD, change working or default directory.

L Bye, Logout server
F Finish, Exit server, but do not log out
E Erase, delete files on server system
D Directory query
U Disk space usage query
T Type a file onto local kermit
R Rename file(s) on server system

K Copy file(s) on server system
W Who's logged in, as in sho sys, sy/s, dev tt
M Send a terminal message to a user
H Help, the server responds with commands it can do
Q Server status query
P Program, run a program
J Journal
V Variable, alter a Kermit setting

C Execute host command. The host command follows in
the data field.

Note that some of the generic server commands, as well as the C packet, may not be feasible for a given environment. For instance, the REMOTE LOGIN command, which sends the generic I command to the server, can only be done under systems that allow you to dial up and start a Kermit without logging in; the generic U command (disk space) is meaningless under some systems (like RSX) unless one wants the free space on the entire volume. No Kermit server will abort on receiving a packet it can't execute, it will simply send an error packet with an informative message saying it can't process the requested function.

An example of a Kermit-65 kermit telling a PRO Kermit-11 server to expect a file follows. The Kermit-65 command was "Send foo.txt"

(0)Atari sends: * S~# @-#Y(
(0)Pro sends: 0 Y~* @-#Y1~* ~T
(1)Atari sends: *!FFOO.TXTE
(1)Pro sends: #!Y?
(2)Atari sends: S"DThis is a test file#M#J
containing two lines.#M#JU
(2)Pro sends: #"Y@
(3)Atari sends: ##ZB
(3)Pro sends: ##YA
(4)Atari sends: #$B+
(4)Pro sends: #$YB

In packet zero, the Kermits exchanged information regarding their capabilities. The Atari sent an 'S' packet with the data for its

maximum packet length, default time out, number of pad characters to follow a packet (none, hence the space), use a null for padding, end of line terminator (a CR + 32), the prefix character for control characters, and a 'YES' to say the it can prefix eight bit characters with the default. It doesn't send any of the extension fields, like indicators for multi-byte CRCs, file header info etc. In packet 1, the Atari sends the filename the Pro should use for the file it creates. The Pro then sends the acknowledgement. In packet three, the Atari sends the first (and only for this file)

packet of data. Note that the sequence #M#J is a carriage return/line feed sequence with 100 (8) xored into each character. The '#' character informs the other Kermit that it must xor the next character with 100 (8). In packet three the Atari sends an EOF packet, the Pro acks it. In packet four, the Atari sends a break packet which tell the Pro that no more files (of a possibly wildcard group) are coming and the Pro Kermit acks the break packet. The Pro kermit then enters the server idle state. More specific information regarding Kermit packets and state transitions can be found in the references listed at the end of the article.

Future directions

With the advent of packet switched networks and satellite communications the Kermit protocol will likely be extended to increase efficiency over such links. The main problem is the half duplex nature of Kermit, the packet acknowledgements can take up to several seconds in transit thus drastically reducing the throughput. There are several possibilities under discussion and a standard should be appearing shortly.

Summary

With the knowledge that there are Kermit implementations for most personal computers in use it becomes apparent that the Kermit standard is well worth looking in to.

(End of protocol description)

For more documentation on what Kermit protocol is all about, see the extensive doc available from the Kermit folks at CU20B.ARPA.

> appropriate pins on the ST the trakball works like a mouse.

I stand corrected. I have a Wico trakball, which won't do this.

Tidbit: the Wico trakball for the Odyssey II game system works perfectly well on the Atari 8-bits & STs as a joystick, and may possibly be purchased for amnormally pithy amounts from dealers who don't know this & think "almost noone has an Odyssey, I'd better sell that trakball cheap."

>

While your way should work usually, here is a different way. This is what
Turbo-Basic does before returning to DOS:

1. Clear locations $D200-$D207 (audio registers)
2. Close IOCBs 1-7
3. Jump indirect through DOSVEC ($000A).

If you have done interesting things with the screen, it might be even better
to refine step 2:

2a: Close all IOCBs.
2b: Open IOCB 0 for screen editor.

Of course you can skip step 1 if you have not done anything with the
audio registers, and it may be that DOS (some DOS) will do the equivalent
of steps 2a and 2b after you return.

650. LittleLister/save paper & time

Newsgroup: comp.sys.atari.8bit
Date: 1987-10-25 21:27:26 UTC
From: curzon@kaoa01.dec.com
Message-ID: <11961@decwrl.DEC.COM>
Source record: 117504

This is a little program I have found useful for printing out text, especially Action! source listings, and saving time & paper. It may be useful for other text printing jobs too, e.g. sources that are saved to disk in ATASCII text form. Check the LL.DOC file included below for a quick rundown.

PRINTER OUTPUT OPTION

Littlelister composes columnar output in memory. It can be used with any printer, to print any size of input file. I wrote it for my 1027, but it works even better with my new NX-10 printer. For maximum speed printing, it can be set to represent "unprintable" bytes with combinations of printable ones; full graphics ATASCII printing is also possible using G: (see below).

THE CODE

The UUencoded binary file follows in a separate message. If it doesn't make it through some gateway in its travels, I will mail a copy direct on request. For least frustration, use the YAU UUdecoder to decode it. It seems some of the other decoders might require extra padding on each line; I used YAUE to encode it. Action! sources also available on request, due to length I haven't posted them... yet)

(Thanks to JRD: YAU and YAUE are very nice tools; they work fine with SpartaDOS in both command line and prompt modes.)
(Thanks also to Bruce Langdon, for the ideas in his PRINT.ACT program posted to Usenet some time ago)

----------LL.DOC----------

LittleLister 2 features:

INPUT: file formatted in a single column, or unformatted.

OUTPUT: formatted in n columns, [0 < n < 256] with several options.

Use with any DOS:

With a command line DOS such as SpartaDOS or DOS XL, type

LL [input [output]]

Used with this command line, LL
starts without presenting a menu; the
variable settings last SAVED will be
in effect. File specifications may
be used for input/output, and the
"D:" prefix is assumed by default.
Output defaults to "P:" (printer).
"LL" alone will bring up the menu.

With other DOS's, just load LL
like any other binary file, and work
from the menu.

Variables include:
----
*input file
*output device (default = P:)
*starting page number (default = 1)
page pause
output options
ASCII
(^ prefixes control characters;
@ prefixes inverse characters;
few special chars output in hex)
HEX
(all bytes represented in HEX -
e.g. $FF)
ATASCII
(no transformation of bytes from
input file)
output width
output page length
number of columns
column width
margin between columns
filler lines at top and bottom

* - not included in variables SAVED
by menu choice 'S'

Other features:

-you can save special configurations
of LL.COM, by using 'S' option
and copying to a different *.COM
filename
-outputs page header with filename,
and page number (if you select
at least 4 filler lines before
the first text line)
-allows any single column file to be
produced in multiple columns:

program listings, database output, utility output, etc.
-chops off blanks at the end of each text line (useful for trimming Action! source code)
-produces output to any device (but page pause is disabled when output is to disk file)
-try ATASCII output to G: device, the graphics printer utility for Epson/Star & compatibles released by Analog in October 1985 issue - very nice ATASCII output.
-Action! programmers may output HEX to disk to transform binary files (character sets, code blocks) to blocks for the Action! compiler.

Version 2 notes:

- added HEX output
- compiled high enough to allow use of the G: device by CF Johnson, for pretty graphic ATASCII output.

From: curzon@kaoa01.dec.com
Message-ID: <11964@decwrl.DEC.COM>
Source record: 117356

Addendum #2 to the Littlelister binary sent to the net in UUencoded
form. Here is the UUDECODE data you should be given by YAU when you
decode the binary file LL.COM:

byte count: 7147
checksum: #x0A27

If you have a different figure, it will likely be caused by a corrupted
input file. It may be possible to directly mail you a better copy of
the file, let me know if you want one.

>
>Mike

I replaced both diodes, CR15 and CR16 I think are their numbers. OThe voltage across them is about 5V. Does this sound right? When I put a disk in the drive and close the handle, the drive makes a noise for only a moment, (you know the sound, whatever it is). The busy light stays on, but the disk never turns and when I turn on the computer I get the disk boot error message.

It costs $90 to have drives repaired around here and you can get a new one for around $135-140. It seems that they're a throw away item if one can't fix it themself.

To answer your question, I think it was CR15 that was the diode that was cracked and the first one replaced.

Have any other suggestions? Your considerations are greatly appreciiated.

Thanks

Rick Nelson

Here's a bit of advice that just may solve your problems. In the
above I noticed that you have replaced the diodes and are now on the lookout
for possible bad solder connections.

My suggestions is that you replace the whole Bridge Rectifier system, and
also the 5 Volt regulator. I have had many a 1050 drive in my hands for repair
and for the most part the 5 volt reg was the problem. The voltage on the side
of the diode, (CR15 I think -- the one comming directly from the bridge)
should be about 22 volts. If it's low, you probably have a leaky diode in the
bridge, so just replace all 4 diodes in the bridge. Replacesment of the 5 volt
regulator is cheap insurance, so I would also opt for that. Just rememer to
get the rigth polarity regulator. Wouldn't want to pop the wrong voltage
potential around the drive, which would make the whole situation worse.

Hello there! I'm very new to this wonderfull thing of gateways, and was wondering about some things about my atari 8-bit..
A) How can I go about obtaining A working copy of Kermit-65? I have a doc file for an old version of it, and it seems very good, and I would like to get my hands on it.. Right now I have to use Chameleon to access the vax/vms system, and most other people are using vt100, and, well, uh, Chameleon dosen't support vt100.. At least Moria works with vt52..
B) What are the files YAU and YAUE? I noticed in the info-atari8 list i found that I would use that program to somehow extract LL.COM from the text file?? Please explain and tell me how to obtain these programs also, thanks.
[I already have LL.*, I found it Arc'ed on a BBS I call..]

DECEMBER 1987 ANTIC TOC
Theme: Printer Power

page article

9 I/O BOARD
Letters from Readers.
10 NEWS UPDATE
ANTIC tests the newest Atari hardware.
14 GAME OF THE MONTH: DUNGEON ARCADE
An epic-scale fantasy role-playing adventure that offers elements of arcade action when you fight monsters in the 40-room dungeon. BASIC.
17 COMMUNICATIONS: ICONVERTER
A program that converts any Print Shop icon directly to ATASCII graphics. A whole new treasure trove of online art is now available.
19 NEW PRODUCTS
A description but not a review of several new products available for the Atari computers. This months list include Graphics Companion I (Datasoft), Lightspeed C, Classy Chassy and Time Bomb (Clearstar Softechnologies).
24 PRODUCT REVIEWS
Software
First XLEnt Word Processor V2.1 (XLEnt Software)
Awardware (Hi Tech Expressions, Inc)
30 APPLICATIONS: SCIENCE STATISTICIAN
Just what you need for all those laboratory experiments where you have to calculate averages and standard deviations for your results. BASIC.
37 NEWS STATION PAGE-DESIGNER
A review of News Station and News Station Companion from Reeve Software.
40 P.S. ENVELOPE MAKER
Now you can make an endless supply of custom-addressed envelopes just the right size for your Print Shop cards.
41 PRINT SHOP POWER TRICKS
Master advanced PS techniques not documented with this popular software. Mix upper and lower case letters, place multiple graphics on the same page, etc.
42 MORE ICONS FOR PRINT SHOP
Sources for public domain and low cost icon disks.
44 DESIGNER LABELS MAIL-MERGE
A short patch for Designer Labels (ANTIC 4/87) that allows you to use PS icons to decorate your mailing list labels.

51 TURBOBASE BUSINESS SOFTWARE
A review of MicroMiser's TurboBase Integrated Business
Applications software. This company really knows how to
support its users.

**********BEGIN THE ST RESOURCE SECTION**********

54 ST PRODUCT NEWS
New Products (description only)
This months list include: Plutos and Q-Ball (Mindscape,Inc),
Hacker and Little Computer People--lower prices (Activision,
Inc), MasterCAD (INDI C.A.), MIDI Maze (Hybrid Arts, Inc),
SCAD (XETEC, Inc), IMG SCAN (Seymor-RAdix), Vegas Gambler,
Vegas Craps and Club Backgammon (Logical Design Works, Inc)
and Athena II (Iliad Software, Inc).
55 ST PRODUCT REVIEWS
Software
ST Wars (Miles Computing)
1st Math (Elmer Larsen Stone & Associates)
Memory Master and My Letters (Elmer Larsen Stone & Associates)
Numbers and Words (Elmer Larsen Stone & Associates)
Shanghai (Activision, Inc)
Hardball (Accolade Software)
57 MORSE CODE TRAINER
This program (actually 2, one for the ST and one for 8bit
computers) will take text from a file and send it to you
as morse code. It also prints the text to the screen so
you can see your mistakes as it sends.

**********END THE ST RESOURCE SECTION**********

61 SOFTWARE LIBRARY
This section contains all the program listings for the
articles in this issue.
82 TECH TIPS
This section is a collection of tips and short
programs from readers or collected from various Users
Groups newsletters. This months is all sound effects.

Coming next month: The sixth annual Shoppers Guide.

Comments: The disk bonus this month is ANTIC PUBLISHER for the 8bit owners.
It is a starter desktop publishing program that gives you some
of the key capabilities of Print Shop and Newsroom. It features
pull-down menus and joystick control.

662. FROST and Turbo BASIC questions...

Newsgroup: comp.sys.atari.8bit
Date: 1987-10-29 22:49:47 UTC
From: jhs@MITRE-BEDFORD.ARPA.UUCP
Message-ID: <8710292249.AA12047@mitre-bedford.ARPA>
Source record: 117366

Does anybody know if the Turbo BASIC compiler and runtime system work

(a) on an 800 or upgraded 400?

(b) on an XL/XE under SpartaDOS or DOS-XL or any other
DOS that uses portions of the RAM under ROM?

I am wondering whether to bother sending out the compiler and runtime
system to people who request FROST BASIC. In general I have not, but somebody
ought to try out the above combinations.

-John Sangster, jhs@mitre-bedford.arpa

You might try (with no guarantees)

American TV (415) 352-3787

CSC (Hightstown NJ) (609) 448-8889

Applied Computer Associates 1-800 4-ATARIS (428-2747)

If you strike out, and need specific questions answered, I'll try to find time to look them up for you. Somebody oughta ask COMPUTE! if they will release the book into the Public Domain so die-hards can copy it for friends.

-John Sangster / jhs@mitrebedford.arpa

10/30/87

I have enjoyed the Atari Digest and appreciate seeing it posted on the network.

Can you help me locate an Atari 825 printer? My preference is a functional device, but would accept one for parts. I could also use a Centronics 737 or Radio Shack Model IV printer.

I appreciate any help you may be able to provide.

Thank you,

Hugh Wells

FROST BASIC will work on a 800 or 400 as well as an XL/XE computer.

Turbo BASIC will only work on an XL/XE and gives about 12K more RAM.

> (b) on an XL/XE under SpartaDOS or DOS-XL or any other
> DOS that uses portions of the RAM under ROM?

Turbo BASIC will not work with any DOS that uses the RAM under the
ROM.

FROST BASIC will only work with the DOS that is supplied on it's disk.
The compiler and DOS are very closely tied (I tried unsuccessfully to
de-couple them), if fact they are appended together as one binary file,
and the compiler uses hard coded vectors to interface with the DOS.

670. 1050 disk format

Newsgroup: comp.sys.atari.8bit
Date: 1987-11-03 18:41:00 UTC
From: Makey@LOGICON.ARPA
Message-ID: <8711031041.8580.Makey@LOGICON.ARPA>
Source record: 117374

I am writing an exerciser for my (unmodified) Atari 1050 disk drive, and I would like to know what the "worst cast" pattern is that I should write to the disk to test for bad media.

For the uninitiated, the worst case pattern is like alternating ones and zeroes, except that the particular method of encoding the ones and zeroes on the disk may mean that a different pattern is actually the "worst" case. Thus, even if you don't know which pattern is worst you could help me if you could tell me how ones and zeroes are physically stored on the disk. Thanks in advance.

671. Repost: CC8 documentation

Newsgroup: comp.sys.atari.8bit
Date: 1987-11-04 03:38:59 UTC
From: smk@cbterra.ATT.COM
Message-ID: <3737@cbterra.ATT.COM>
Source record: 117375

[This is a repost of the V2.3 CC8 documentation. I've fixed some grammatical and spelling errors and appended the notes for V2.3b, the last posted version of the compiler. - Steve]

CC8 DOCUMENTATION

This compiler is an upgraded version of the Deep Blue C (DBC) compiler which supports more features of standard C and is much faster. It generates the same kind of pseudo code as DBC and ACE C and can be used with either's linker and runtime engine. I recommend using ACE C for its speed and expanded features. This document gives a brief overview of the extended features of the compiler along with its limitations.

This document is not intended as a C tutorial, nor is it intended as a tutorial for DBC or ACE C. Features such as assembly language protocol, built-in routines, and floating point depend solely upon the type of linker and runtime system you are using, and NOT upon this compiler.

PREPROCESSING

CC8 supports all preprocessor functions except for #line. This includes macro functions, #ifdef, #ifndef, #if, and #undef. In addition,

o #include files may be nested (currently only 2 deep)

o no restriction on placement of comments

o the TAB character may be used as white space.

o predefined symbols __LINE__ (replaced by current line number) and __FILE__ (replaced by current file name).

o #ifdef, #ifndef, and #if may be nested (5 deep maximum).

Caveats:

- "bizarre" usage of #define macros may not work as expected (or at all)

- in the "skipped" section of an #ifdef-#else-#endif group, comments are not processed. Thus it is not a good idea to "comment out" #else's or #endif's.

VARIABLE DECLARATIONS

CC8 supports more complex type constructions than DBC or ACE C, e.g., pointers to pointers. In addition, the types struct, union, and enum have been added and variables can be declared static.

o multidimensional arrays may be declared.

o functions may be declared as returning char, int, or pointer to anything. Pointers to functions, arrays of pointers to functions, etc, may be declared. Note: a pointer to a function must now be used correctly:

(*pf)();

not

(pf)();

o variables declared as type "enum x" are really declared as type "int"; the name "x" is ignored. Note that user assignment of numbering scheme is implemented, e.g.,

enum colors $(red = 2, white = 0, blue $);

assigns red = 2, white = 0 and blue = 1.

o external array declarations of the form

extern int array_name[];

are now valid.

o in expressions, the sizeof and type cast operators may be used.

Caveats:

- no float/double declarations (but a limited floating point is available when ACE C's linker and runtime engine are used)

- all struct/unions must have a tag name

- all global symbols, struct/union tags and components are drawn from the same name pool.

- no bit fields

- identical declarations of a variable neither cause an error nor do they work reasonably. For example,

int a; int a;

will silently declare "a" twice and confuse the linker.

COMPILE TIME EVALUATION OF CONSTANT EXPRESSIONS

CC8 supports a limited form of compile time evaluation of constant expressions. A constant expression is defined as any expression containing integer constants, character constants, sizeof, or a constant expression separated by one or more operators in one of the following groups, "|", "^", "&", "==", "!=", ">> <<", "+ -", "* / %", or prefixed by one of the unary operators, "-", "!", "$-". Evaluation follows normal rules of operator precedence

and can be overridden by parentheses. Examples:

x = 12*24 + 13; => x = 301;

x = 12 + 13 + y; => x = 25 + y;

x = y + 12 + 13; => x = y + 12 + 13; (1)

x = y + 12*13; => x = y + 156; (2)

x = y + (12 + 13) => x = y + 15; (3)

1. compiler "gives up" after finding non-constant 'y'.

2. '*' is in a different precedence group than '+' and thus "12*13"
appears to the compiler as a separate expression.

3. Parentheses force compiler to treat "12 + 13" as a subexpression.

Constant expressions may be used in array declarations, initializers,
and #if.

INITIALIZERS

CC8 supports initialization of global variables of type char, int,
pointer, array, struct/union, and enum. The syntax is a subset of that
allowed by standard C.

Rules:

1. Simple types (char, int, pointer) can be initialized by
a constant expression. The constant expression must not
be enclosed inside $($). Absolutely no type checking is
done. The definition of constant expression is extended
to include:

o address of static variable
o static array names
o function names
o "character string"

2. Aggregate types can be initialized by the following
construct:

$(init-element-1, init-element-2, ..., init-element-m $)

a. if fewer initializers than elements appear, the rest of
the aggregate is initialized to zero.

b. if the number of elements of an array is not specified,
then it will be set to the number of initializers.

c. a character array may be initialized by a string.

Examples:

int x = 23*22;

```
char *p = "hello";
char q[10] = "hello"; /* q[6] ... q[9] are set to '\0' */

int f();
int (*pf)() = f;

/* array bound set to 5 */
char *weekdays[] = $( "Mon", "Tues", "Wed", "Thu", "Fri" $);

struct x $(
char *symbol;
int value;
$);
struct x tab[] = $(
$( "word1", 4 $),
$( "word2", 8 $),
$( "word3", 13 $)
$);
```

Caveats:

- local variables cannot be initialized (bad programming practice anyway)

- unions cannot be initialized (properly, that is)

GOTOS AND LABELS

CC8 supports the dreaded goto statement and labels. Note: the compiler cannot distinguish between labels and local variables.

ERROR HANDLING

Error messages are printed in the typical Unix C fashion:

file-name, line #: error message

In addition, the line causing the error is printed. Note: if the error occurs near the end of a line, the compiler will usually flag the next line.

This compiler, like DBC and ACE C, does not know how to intelligently recover from syntax errors. For this reason, the compiler will halt compilation after 8 errors.

The compiler no longer exits directly to DOS on fatal errors (e.g., too many errors) so that the user may jump directly to an editor using the command line feature described below.

I would appreciate knowing if the compiler hangs after finding an error or a certain sequence of errors.

INTERNAL LIMITS AND TABLE SIZES

Lest we forget this is not a 48K 8 bit implementation of C, here are some of the more important limits:

1. 7000 bytes of "global space" -- shared by:

- macro definitions
- each unique non-macro symbol name (15 bytes + length of symbol)
- global symbol type info

2. 256 bytes of "local space"

- local symbol type info
- only 128 local symbols may be declared.

3. A source line may not be longer than 254 characters after macro expansion. WARNING: this limit is not checked!

4. An expression cannot generate more than 512 bytes of p-code instructions. An expression violating this limit would be ridiculously huge. WARNING: this limit is not checked!

5. 512 bytes of "string space"

- This table was 3000 bytes in DBC and probably ACE C too.
- A way around the size constraint is to use initializers:

```
char dummy1[] = " ... ";
char dummy2[] = " ... ";
...
```

6. 2300 bytes of stack space

The compiler has been written to conserve stack space, so stack overflows should be a rarity. This is fortunate because -- WARNING: this limit is not checked! Stack overflow will overwrite screen memory (but it's possible compilation will complete normally).

7. #define macros may have up to 128 arguments.

CC8 uses memory from MEMLO to MEMTOP and locations $480 to $6FF. MEMLO must not exceed $2BFF.

SPEED

CC8 is much faster than DBC and slightly faster than ACE C (15% - 30% depending on type of program). Compilation time is affected most by the presence of #defines. You should expect compilation times of 15 to 30 seconds for small programs, and up to 2:00 for large programs with many #defines. Larger source files are possible, but run the risk of running out of internal table space. Some sample times:

Program Description	SC	ACEC	DBC
238 lines, no #defines	58	80 (1)	551
same, one #define	66 (2)	77 (1)	-
482 lines + 222 #include'd many #defines + comments	107	-	-

Note: these timings were made on an 800xl with a 1050 running DOS 2.5 with write verify on.

(1) I can't explain this anomaly.

(2) The reason one #define makes so much difference is that the compiler takes advantage of the zero #defines to skip part of the pre-processing phase.

COMMAND LINE FEATURES

For users of DOS' that take a long time to reload (such as DOS 2.X), a way to load and run files directly from the command line has been provided.

o ^L<RETURN> runs file called "D1:LINK.COM"
o ^Lfilename<RETURN> runs file called "filename"
("D1:" and ".COM" default)
o ^E<RETURN> runs file called "D1:EDIT.COM"

Note this feature is in its infancy.

1. The control characters print as their equivalent graphic characters.

2. ^L runs the ACE C and DBC linkers, and ^E runs SpeedScript. Nothing else has been tested.

3. "Theoretically" the load routine understands INIT addresses.

MISCELLANEOUS

Switch statement handling has been reworked. The last clause need not end in "break", "continue", or "return". In addition, the "default" clause need not be the last (this was a bug in DBC). On the down side, you are limited to 100 "case"s per switch statement, and switch statements may be safely nested only four or five deep. I'll wait until someone complains before I attempt to fix this.

More efficient code is now generated for the && and || operators.

Local variables may be declared at the beginning (not just anywhere as in DBC) of compound statements. However no two local variables declared inside a function may have the same name (this is a departure from standard C). Variables declared with a storage class of "register" are the same as "auto".

All C reserved words are recognized by the compiler. Thus a variable cannot be named "float" or "entry."

Characters with the 8th bit set that are not part of character constants, strings, or comments will cause the compiler to crash.

FASTC.COM should work on CC8 output.

I have been told that the compiler also works with the LightSpeed C linker and runtime engine.

FUTURE

1. Improve error handling

2. Add ability to pass files to compile in command line for SpartaDOS
and compatible DOS.

ACKNOWLEDGEMENTS

Thanks to Harald Striepe and Marc Appelbaum for their beta testing.

Thanks to Mark VandeWettering and Greg Koolbeck for their input.

AUTHOR

Steve Kennedy

1895 Fountainview Ct
Columbus, OH 43232

cbosgd!smk (seismo, decwrl, and ihpn4 know about cbosgd)

The following is a list of fixed bugs, enhancements, and known problems:

Bug fixes:

1. Empty expressions in for statement accepted, i.e.,

for(;;;) $($)

2. Constant expression are now valid after "case", i.e.,
"case 2*3." (fixes "case -1:" problem)

3. "*a" if a is an array no longer generates an error.

4. A function argument declaration of "type var[]" is now
converted to "type *var." Previously, the compiler generated
bad code which caused a lock-up when the resulting program
was run (e.g., programs using "getname()" in ACECIO.C).

Enhancements:

1. The expressions "a[x]" and "x[a]" are both valid and
equivalent provided one of x or a is a pointer or array.

2. structs without explicit tag names are now legal, i.e.,

"struct $(.... $) y;"

3. The compiler now recognizes the keywords "short" and "long."
Note that "int" = "short" = "short int" = "long" = "long int"
= 2 bytes. "Long" declarations produce the warning
"long == short."

4. The compiler now recognizes the keyword "unsigned" and
will generate unsigned comparison code for <, <=, >, or >=
when one or both operands are unsigned.

Caveats:

- You'll have to write your own routines to print these
correctly (no %u in ACE C or DBC printf).

- I'm not sure *, /, or % work properly on unsigned numbers.

Known problems (send mail or post if you want to add to the list):

1. Not all escape sequences recognized by ACE C are recognized by
CC8. (\u, \d, \l, \r, \e)

2. Compiler doesn't like "register x" although it will accept
"register int x." Note that "register" doesn't do anything
special anyway.

In one of the last Info-8 Digests (I have to rely on the digest's),
the yau/yaue/etc. programs were in the middle, and I had to read thru them
to get to the rest of the digest.. Do you think you could be moving the
programs in the digest to the end of the file?? It would be much better, I think
Also, In the headers, of the program, like the ---------cut-here-for-xxxxxx.xxx-
-
Have you thought about putting in something like --%%-----cut-here-etc..
That way I could use the search command of my vms system, look for --%%
to get the lines for the beggining and ends of the different files, so I'm not
searching for them in the editor.. I suggest something like:
--%%----cut-here-for-XXXXXXXX.XXX--------------------
BLAH
BLAH
BLAH
--%%----end-of-XXXXXXXX.XXX-------------------------

I just think those two ideas would make things a bit easier for the readers?

-Uck! [Errol Cilen] V111MFQ6@UBVMS.BITNET

/s
What am I thinking?

673. Re: 1050 disk format

Newsgroup: comp.sys.atari.8bit

Since the format itself is untouchable on a stock 1050, your
only option would be to use worst case data.

The TRS-80 always used the Hex byte E5 to fill all the unused
sectors on a track. This was the worst case data you could
get, and helped verify flaky disks. Since the TRS, Atari,
IBM and ST all use (cough) the same disk format (well, I us
the TRS to copy disks for all of the above!) it would seem
a safe assumption that this would prove close if not it.

Perhaps the 800 version will, but the XL version won't.

"Wow, it never did THAT before."

Date: 3 Nov 87 10:41 PST
From: Jeff Makey <Makey@LOGICON.ARPA>
To: info-atari8@SCORE.STANFORD.EDU
Subject: 1050 disk format

I am writing an exerciser for my (unmodified) Atari 1050 disk drive,
and I would like to know what the "worst cast" pattern is that I should
write to the disk to test for bad media.

For the uninitiated, the worst case pattern is like alternating ones
and zeroes, except that the particular method of encoding the ones and
zeroes on the disk may mean that a different pattern is actually the
"worst" case. Thus, even if you don't know which pattern is worst you
could help me if you could tell me how ones and zeroes are physically
stored on the disk. Thanks in advance.

Yes. There is a special 800-only version.

>

> DOS that uses portions of the RAM under ROM?
Perhaps the 800 version will, but the XL version won't.

Subject: Several things
To: Info-Atari8@score.stanford.edu

A while ago, I posted an upgraded, bug-fixed etc version of Kermit-65.
I haven't seen it appear in the archives, nor have I seen any mail about
it. Does anyone know what happened? Did it disappear into hyperspace?
I'll repost it if so.

Second thing: I'm whipping up a new assembler for use in the C compiler
project, and was wondering what sort of macro syntax anyone prefers?
In particular, what does MAC/65 do? I gather from reading mail that a
number of folk like that one. Any other favorites? Any particular
kinds of macro capabilities in demand?

Finally, in digging back thru old mail, I discovered a rumor that
someone was going to come up with a relocatable object format. I
haven't seen anything about it since; does anyone have any info about
such a thing? If not, I'll finish my own design and use that.

Thanks for any feedback.

I am getting desperate and have exhausted local possibillities for obtaining
a diagnostics diskette for the 1050 drive. Does anyone know how to get one of
these critters?? I have posted once before but to no avail, and a drive that
reads fine but writes seemingly random errors is making me crazy. Bringing
it to the local repair shop is out since they "fixed" it once already, and
I really don't want to hand over any more dough to these guys. ANY help would
be greatly appreciated. Please respond by email unless you may have a great
revalation that may help others with similar problems with "repair" shops.

681. Object code relocator

Newsgroup: comp.sys.atari.8bit
Date: 1987-11-05 15:08:42 UTC
From: curzon@kaoa01.dec.com
Message-ID: <12097@decwrl.DEC.COM>
Source record: 117385

RE: Object Code relocator.

The only thing close to relocatable code generator for Atari 8 bits that I have heard of, is a back-end thing done by Keith Ledbetter. It is takes as input 2 object files compiled at origins $102 bytes apart, and attaches some relocating code. It imposes a few constraints on how to reference memory. It also doesn't take into account SpartaDOS and DOS XL (I believe they will try to enter the code at the load point after processing the INIT and RUN vectors like Atari DOS... which will crash the system unless you "manually" put an RTS at the load-point, I think)

Sounds like John Dunning is going to brew us up another nifty tool here; in the meantime does anybody want Keith Ledbetter's relocatable code generator? I can post it with Docs within a week if anybody wants...

Subject: Several things
To: Info-Atari8@score.stanford.edu

A while ago, I posted an upgraded, bug-fixed etc version of Kermit-65.
I haven't seen it appear in the archives, nor have I seen any mail about
it. Does anyone know what happened? Did it disappear into hyperspace?
I'll repost it if so.

Second thing: I'm whipping up a new assembler for use in the C compiler
project, and was wondering what sort of macro syntax anyone prefers?
In particular, what does MAC/65 do? I gather from reading mail that a
number of folk like that one. Any other favorites? Any particular
kinds of macro capabilities in demand?

Finally, in digging back thru old mail, I discovered a rumor that
someone was going to come up with a relocatable object format. I
haven't seen anything about it since; does anyone have any info about
such a thing? If not, I'll finish my own design and use that.

Thanks for any feedback.

To: info-atari8@SCORE.STANFORD.EDU
Subject: 1050 disk format

I am writing an exerciser for my (unmodified) Atari 1050 disk drive,
and I would like to know what the "worst cast" pattern is that I should
write to the disk to test for bad media.

For the uninitiated, the worst case pattern is like alternating ones
and zeroes, except that the particular method of encoding the ones and
zeroes on the disk may mean that a different pattern is actually the
"worst" case. Thus, even if you don't know which pattern is worst you
could help me if you could tell me how ones and zeroes are physically
stored on the disk. Thanks in advance.

I recently purchased Kyan Software's Pascal compiler, and I must admit I'm a little disappointed. The documentation is fairly thorogh in terms of Pascal and actually writing programs, but the entire section on how to get the environment (Editor, Compiler, Assembler, Utilities) seems to refer to an earlier form of the system - the user interface is almost completely DIFFERENT from what the manual says. I was able to work it out because I have used an Atari (and other computers) for many years and knew roughly what SHOULD need to be done, but I can see a lot of novices having trouble with this system as-is.

My other major complaint about Kyan Pascal is that nearly EVERYTHING on the system is in a separate file which MUST be present on the SAME disk as the program-to-be-compiled. This leaves me with about 80 sectors free to use for Pascal source, intermediate Assembly source, and final executable file. On top of that, many of the more useful functions, even minor ones such as "PLOT" and "DRAWTO" equivalents, must be 'included' into your source code from still more - guess what - "required" files.

You with 256K RAM should be all right, though, because there's support for the XL/XE D8: Ramdisk device, leaving you with a little more elbow room than I've got with a single-drive, single-density system.

Personally I'm thinking of sending it back.

Here in diagnostic land, we have always used a worst case
data pattern of -> 6D, B6, DB when testing floppy subsystems. I'm not
sure why this pattern came into being, but I do know that we have been
using this as a standard for many years, and this company is usually
more conscious of it's diagnostics than most other companies.

688. Disk R/W problem - causes?

Newsgroup: comp.sys.atari.8bit
Date: 1987-11-08 18:53:49 UTC
From: cfchiesa@bsu-cs.UUCP
Message-ID: <1448@bsu-cs.UUCP>
Source record: 117392
Cross-posted to: comp.sys.atari.8bit,comp.misc

I've just gotten thoroughly disgusted with my Percom AT-88 SS/SD 5 1/4" floppy drive. It's been screwing up my disks more and more over the past few months, and I finally "caught it in the act" today.

Situation: I copied a large (200+ sectors) file onto a disk which turned out not to have enough free sectors (neglected to check in advance), resulting in error 162 - "Disk Full." Issued "DELETE filename.ext" command. Normal I/O sounds, then repeated "buzz-clunk" of "unreadable sector." Examined disk, found sectors 685 and up unreadable with Error 144, "invalid 'DONE' byte". Tried to patch file by adding next-sector field of 00 (end-of-file), but was unable to write formerly-readable sectors. Was THEN unable to READ formerly-readable sectors. Drive had turned a "good" sector into a "bad" one right before my eyes. Has made many of my disks unreliable.

Error appears to occur primarily with high-end (600 and up) sectors, when it occurs (I was able to write that file to begin with, but glitched when trying to alter it later). NO problem at ANY time with low and mid-range (360's) sectors.

1) I'm hoping this is just a case of a dirty head: hasn't been cleaned or otherwise maintained since I bought the drive in mid-1983. Can anyone offer opinions on the likelihood of this being the cause?

2) Can anyone recommend a drive-head-cleaning procedure or product (with vendor info, if possible)?

3) I use a Q-Tip saturated in rubbing alcohol to clean the heads of my audio equipment; would this be satisfactory for the disk head, or is it more delicate? Would like to know before just TRYING it.

(Would someone, somewhere, please just plain REPLY to this, so that I know it's being seen? I've NEVER had a response to ANYTHING I've posted in the whole time (a month or two) I've been posting to the net. Are you reading me at all, world?)

Appreciatively,

Chris Chiesa, Senior, CS Dept, Ball State University, Muncie, IN

Message-ID: <821350@RPITSMTS.BITNET>
Source record: 117393

I also would like some joystick I/O info. As far as I know, tying
a pin to +5v will signal a 'joystick' up, down, left, right, etc.
This means that impossible joystick movements like up-down are also
possible. I think there is a listing in the Atari manual, but it is
always possible to get a listing by just printing the memory locations
of a joystick port and connecting different pins to the 5 volt pin to
see what value is printed. Don't connect the 5 volt pin to ground...

I doubt it is just a dirty head. Your problem sounds almost identical
to a problem I had on my Corona IBM clone five years ago. It had Tandon ds/dd
floppy drives. The drive would consistently get errors on high track numbers,
and there seemed to be no pattern to it. It was easily reproduceable but never
on the same sector. Wrote fine. Errors occured only on reads. No errors on low
tracks.

The first thing I did was clean the heads and check the speed. You can do
this too. If you physically remove the drive you will notice it should have
a ring of alternating black and white spots on the flywheel. If you watch this
wheel under a fluorescent lamp (You must be in a country with 60Hz power) the
spots should stay still. If they don't, your drive is too slow or fast. This
can be adjusted by turning a pot on the drive logic board... If it is not
marked, you should find out or get a real techie to do it for you.

Your other option is to find one of the many public domain disk testers.
Maybe someone you know has a special disk put out by Verbatim a while ago
that checks rudimantary things like speed, tracking etc... It's not perfect
but if you can find it it could point out what is wrong.

My experience was that you are probably out of luck. My problem eventually
wound up with a disk drive technician, he tried everything he knew on it, he
actually spent many days checking the logic board and everything (In those
days floppy drives were expensinve!). He found zilch. Luckily he didn't
charge me, because the time he spent on it would have been twice the price
of a new drive. My drive tracked perfetly, passed all the analyzer disks
and the logic board was impeccably clean. Under software however, SHAZAP!

It might not be worth the aggravation to fix it. You should be able to find someone with an old floppy drive at an user's group meeting in your region. I have three in my basement... (Including the shazap model :-) and the prices for new ones is certainly cheap(~>$100). The new ones are *quiet* too.

> 3) I use a Q-Tip saturated in rubbing alcohol to clean the heads of my
> audio equipment; would this be satisfactory for the disk head, or is
> it more delicate? Would like to know before just TRYING it.

I was once told that rubbing alcohol had compounds that did not evaporate. I clean my stereo with floppy disk cleaner (:-) because it is the same thing as those horrendously expensive bottles they sell in stereo stores, but a lot cheaper... (a big bottle costs as much as a little stereo bottle)
If anyone can confirm the rubbing alcohol, I would appreciate it.(chemists?)

But be careful, poking your Q-tip in the cramped drive space, you don't have much room, even in a full height drive. $15 at your local computer store could probably save you a lot of headaches. If you insist on Q-tips, make sure you get some extra long ones. The head assembly is not glass but bay be pushed out of alignment by poking around. On some drives the head does not lift enough for a Q-tip to squeeze in. Personally, I'm very scheptical about cleaning heads this way. Commercial kits are so much easier and safer.

As far as commercial kits, make sure you look for a non-abrasive one if you intend to make cleaning a habit. This goes for your VCR head cleaner too. I've seen VCR heads damaged permanently by some of those early abrasive (sandpaper anyone :-) head cleaners. The same technique used to be used by some floppy kits (past tense I hope).

Good luck.

691. LittleLister Action! source

Newsgroup: comp.sys.atari.8bit
Date: 1987-11-10 14:29:43 UTC
From: curzon@kaoa01.dec.com
Message-ID: <8711101429.AA04064@decwrl.dec.com>
Source record: 117395

For those interested in the Action! language, this is the LittleLister source code. In order to represent the non-ASCII characters, it was prepared by LittleLister itself. It prefixes the inverse video characters with a "@" -- so it will need some editing to run...

If you are checking out compiled languages for the 8bit, you will note Action! has similarities to Pascal and C, as can be seen in this example. And it is faster in compilation, and compactness of code produced than any other hi-level language on the 8 bit. A pleasure to use, comes with a good built-in program editor.

Potentially interesting things:

```
procedure GetAD(), PutAD() - block I/O suggested by Bruce
Langdon
procedure Get_Wds() - gets the words from the command line for
Sparta DOS, DOS XL as well as detecting whether
the DOS in use has command line capability
procedure End() - goes to DOS (not too tricky), but
this procedure also keeps the stack clear, regardless
of how deeply nested you are when you call it.
procedure Clr_Dos() - a work around. I found that if I returned to
SpartaDOS, when the last disk access was for write or
update, I often got some out-of-control disk writing.
This function ensures that the last disk access was a
read before we exit to DOS. [If anybody can explain, I
would like to know what causes this!]

692. Re: Stan Lackey's question about joystick I/O

Newsgroup: comp.sys.atari.8bit
Date: 1987-11-10 15:16:04 UTC
From: saulnier@cg-atla.UUCP
Message-ID: <1060@cg-atla.UUCP>
Source record: 117396

The joystick data lines are ACTIVE LOW. If nothing is connected
to these ports, you will read $FF from the joystick register.
I would not advise connecting +5v to ANY of these lines. I'm
not sure if any damage would result, but it's not a good idea
anyway. The Atari Hardware manual has the pinout for these
ports. I usually read directly from the regiter rather than
the shadow locations. In my 130XE, both data ports can be
read from the same register ($D300 I think), with port 0
being the lower nibble and port 1 the upper nibble.

Anyway, if you want to find the data lines, connect GND to
the different pins and read the register or shadow.
Better yet, at your request, I will post the pinout for
the port and requirements for reading/writing this port.

693. Turbo BASIC Compiler and Runtime System.

Newsgroup: comp.sys.atari.8bit
Date: 1987-11-10 15:44:36 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8711101544.AA14984@mitre-bedford.ARPA>
Source record: 117397

Mark:

Are you SURE that there are a special version of the COMPILER and RUNTIME system for the 800? I was the guy that Ulrich Lange of West Germany mailed the 800 version of the INTERPRETER to (called FROST BASIC), and I have distributed it on the net and via disk to many people. However, I have never seen any version of the COMPILER and RUNTIME system other than the one that comes with Turbo BASIC XL. My question was whether or not these will work with FROST BASIC.

If you have access to a compiler and runtime system specifically for FROST BASIC, I think that would be of interest to the net.

694. xmodem

Newsgroup: comp.sys.atari.8bit
Date: 1987-11-10 16:17:48 UTC
From: john1233@csd4.milw.wisc.edu
Message-ID: <3448@uwmcsd1.UUCP>
Source record: 117398

We have a local x-modem utility here at UW-Milwaukee and every
time I try to use it with my 8-bit Atari I have trouble.

When I upload (in ASCII) the unix machine doesn't recognize
the Carriage Return.

When I download (also in ASCII) everytime there should be a CR
a capital D is in the text.

I have never tried going into ATASCII because I didn't think it would
work. Any suggestions?

695. ** Kyan Pascal **

Newsgroup: comp.sys.atari.8bit
Date: 1987-11-11 09:03:00 UTC
From: V111MFQ6@UBVMS.BITNET.UUCP
Message-ID: <8711111646.AA00750@ucbvax.Berkeley.EDU>
Source record: 117399

I have Kyan Pascal, and think it's GREAT.

One of the most important things about it, to me, is that it does work with Spartados, even with that weird kix environment.. [It's weird, but it works wonderfully.. I type DOS from KIX to go to SpartaDos, and hit break to go back to KIX. It's wonderfull.. The editor that comes with it isn't that great, but I use Analog's T:EDIT anyways..

The documentation dosen't seem to have any problems regarding the kix environment, as you said, it's not that complicated, but I can't see any problems.. Maybe you got the Apple version docs by mistake or something?

And YOU DON'T NEED EVERYTHING ON THE SAME DISK.. I have the most used files copied to ramdisk (130xe, 64k ramdisk), and then some stuff on drive 2, like include files, and some other things that are used rather often, or just even used, since my 2nd drive is a happy, and happy's don't work well with SpartaDos when you right to them, so.. And then my drive 1, u.s. doubler, is my workdisk, my sources, output files, everything else in between fits on there just fine.. I would imagine you would have to do alot of waiting and disk swapping if you didn't have a ramdisk, and only had one drive, but I have no problems..

696. ReRepost of Kermit-65. 1 of 3.

Newsgroup: comp.sys.atari.8bit
Date: 1987-11-11 16:49:00 UTC
From: jrd@STONY-BROOK.SCRC.SYMBOLICS.COM
Message-ID: <19871111164904.1.JRD@GRACKLE.SCRC.Symbolics.COM>
Source record: 117400

Ok, folks, let's try this again.

I still haven't figured out exactly what happened to the the repost of Kermit-65 version 3.3 that I sent out a few weeks ago; it appears to have made it to USENET, and maybe some other places, but fell into a black hole on its way to the ARPA list. In any event, here we go again.

This is the first of three messages, containing the Doc, KERMIT.UUE and KERMITNR.UUE respectively. Archive maintainers, please replace old versions of Kermit-65 with this one. If you've seen version 3.3 go by previously; my apologies for the confusion, and please ignore these messages.

```

Kermit-65 Manual and bug list Page 1

Kermit-65 for Atari 800s

By John Dunning. Bug reports to me (JRD@Symbolics.COM) via Arpanet.
Other net users will have to find some way of getting mail to Ar-
panet, then use the above address.

Kermit-65 is a port of the kermit-65 available for Commodore frobs.
It runs on 48K Atari 800 family machines. Current version (second
release) is 3.3.

Capabilities:

File transfer, text and binary:

Without going into excruciating detail here, Kermit-65 is a fairly
complete implementation of a user side, using the KERMIT protocol.
It's been tested against Kermit-11 under RSX, and C-Kermit under
VMS and Un*x, and seems to work fine. For a description of what
the KERMIT file protocol is all about, and something about how the
it works, see the 'Kermit protocol' section at the end of this do-
cument.

Terminal emulation:

Glass tty, Vt52, or Vt100. Supports 3 flavors of screen
configuration; Atari standard screen, 80-column pannable
(40-column visible) like VTERM, and 80-column graphics, like
V10SQR. Terminal emulation modes may be used in any combination
with screen configurations, though some combinations won't work
real well; for instance trying to do full-screen Vt100-style ed-
```

itting when using the Atari screen is a good way to lose.

Local file management:

Kermit-65 includes Directory, Erase, and Rename commands, allowing the user to do most kinds of maintainance operations without leaving the program. It also allows you set set the default drive to any value 1 thru 8, so you're not stuck using a single drive for everything.

Typing at Kermit-65:

The command processor accepts command lines, consisting of a keyword, optionally some more keywords, and optional values. Things in command lines are delimited by spaces, and terminated by <CR>. At any time, you may type '?' to get a list of valid completions for the word you're typing. You need not type keywords completely; however much uniquely identifies the word you want is enough. At any time, <ESC> will attempt to complete what you've

typed so far. Note that if you've typed a word, but haven't hit a <space> or <ESC> yet, so that the cursor's at the end of the word, '?' will tell you that there's only the one possibility. Hit a space, then '?', for a list of possibilities for the next word. Some commands are 'defaults' in the sense that if you type something non-unique, and hit escape, and one of the possibilities is a 'default', it will win over the other possibilities. One example of this is 'Send'.
Example: The following illustrates a typical interaction between you, the user, and Kermit-65. The stuff that Kermit types (prompts, echos of partial commands, and help) is on the left, stuff typed by the user is in the middle, and commentary is on the right.

Kermit types: You type: Comments:

"Kermit-65>" Kermit prompts.

"s?" User starts typing a
command starting with
"s", then hits "?" for
help.

"Keyword, one of the following: Kermit prints possible
set show for "s"...
send
Kermit-65>s" and reprompts, with the
partial command.

"et?" User finishes the "set"
command, and asks for
help again.

"Keyword, one of the following: Kermit prints the (one)
set possible completion.
Kermit-65>set"

" ?" User hits a space, then
asks for help again.

"Keyword, one of the following:" Kermit prints possible
(various subcommands of 'set' here) completions for words
that can follow "set"

Kermit-65 Manual and bug list Page 3

Kermit-65 commands:

Bye
Tells the kermit on the other side to log out, and ex-
its Kermit-65.

Finish
Tells the kermit on the other side to exit server
mode, but stay logged in.

Connect
Puts Kermit-65 in terminal mode, using whatever param-
eters are currently set for Terminal and Screen confi-
guration. See 'Set Terminal' and 'Set screen' for
more details.

Quit
Exit from Kermit-65 back to Atari DOS.

Exit
Same as Quit.

Get
<file spec>
Ask the kermit on the other side to send the named
file, using whatever file and protocol parameters are
currently in effect. See 'Set' for more details.
Note that <file spec> may be wildcarded; assuming the
serving kermit allows that. In that case the serving
kermit may send several files; Kermit-65 will try to
receive all of them.

Send
<file spec>
Send the named file to the kermit on the other side.
If the file spec is wildcarded (using DOS FMS wildcard
rules) all matching files are sent. In the latter
case, the Kermit on the other side should be in Server
mode, so that it can deal with a whole sequence of in-
coming files.

Receive
<file name>
Attempt to receive into the named file. Assumes the other kermit is already trying to send it. If no file name is given, Kermit-65 will attempt to get the name from the file-header information coming from the other side. This is the command to use after telling the other kermit "Send <something>".

Set
Baud
(50..9600)
Sets baud rate on the comm port to the supplied value.

Parity
Even, Odd, Mark, Space, None
Sets specified parity for the comm port. See the Atari 850 man for more details on the behaviour of the various parity options.

Word-size
Seven, Eight
Set frame size used for comm port. The default is eight-bit. The preferred value for this depends on what the parameters of the serial line are set to on the other side. In my experience, older systems will tend to use seven-bit configurations, more modern ones will tend to use eight-bits. If you're not sure, it usually works to use eight-bit.

Default-disk
<1..8>
Sets the default disk for all file operations. Legal values are 1 to 8, inclusive.

Rs232-registers
<16-bit hex number>
Directly sets some of the the values used when configuring the serial port. Specifically, the high byte is used as the AUX1 parameter for the XIO 38 (configure translation and parity) and the low byte is used as the AUX1 parameter for the XIO 36 (configure baud rate and word size). This allows settings to be used that aren't covered by the supplied keywords in Baud, Parity, and Word-size.

Debugging
Off, Terse, Verbose
Turns on/off various debug msgs strewn around in the code.

Eight-bit-quoting
On, Off
Turns on/off eight-bit mode quoting in the kermit protocol. The default is off.

Kermit-65 Manual and bug list Page 5

File-warning
On, Off
When this mode is on, Kermit-65 will refuse to overwrite files when receiving. When it attempts to receive a file that's already present, it will alter the filename of the incoming file so as not to overwrite the old version. The algorithm for altering the filename is to replace the extension field of the name with a 2 digit hex number, and retry. If the file still exists, the number is incremented. This repeats until a free name is found, or the extension reaches "FF", at which time the receive is aborted. (I think it's never possible to get that far anyway, as you can't put 256 files on one of these disks)

File-type
Atascii
This is a standard atari text file, and is the default mode. End of line is signalled by the ATEOL character ($9B). When sending, other ATASCII characters are translated to their ASCII equivalents, ie ATTAB ($7F) -> Tab ($09), ATRUB ($7E) -> Rubout ($7F). The file header info generated indicates that a text file is being sent. Receiving one does the opposite transformation.

Ascii
Files are sent/received as ordinary ascii-text. Line terminators are assumed to be CR ($0D) followed by LF ($0A), and are handled in the usual kermit fashion. No translation of data happens. This mode isn't the right thing for regular old text files, but is useful for sending around files that are output in plain ascii from various utilities. For example, I have a word processor program which produces formatted output files in ascii, intended to be dumped directly to a printer. This mode gets them over to my pdp-11's print spooler.

Binary
Data is sent in kermit binary form, no line terminators etc.

Flow-control
On, Off
Turns ^S^Q flow control on/off for the incoming line.

See 'Com port handling', below, for more details.

Ibm-mode
On, Off
Turns on/off 'IBM mode'. This is apparently a standard thing in kermit implementations, made necessary by the wierditudes designed into the blue equipment. This code has been left as is, so it's got some chance of working, but has not been tested.

Local-echo
On, Off
Controls echo mode in terminal emulator. Default is off.

Send
End-of-line, Padding, Timeout, Pad-char, Quote-char, Eight-bit-quote, Packet-length
Sets one of the listed parameters for the transmitting side of the kermit protocol. Padding, timeout (seconds), and packet-length are in decimal, the others (character codes) are in hex. This command is primarily used when talking to a kermit that can't or won't use the standard set of protocol characters for beginning-of-frame, end-of-frame, etc. As such, it's not generally useful, at least I've never seen a kermit that required it. There are things that might come in handy, though. For instance, if you've got an exceptionally dirty phone connection, you might want to set the frame size down from the default of 94. In that case, you might say "Set Send Frame-size 30". Note that Send parameters can be reset by the other Kermit sending one of the kinds of packets that request certain values, so you may have to tell him directly, to get the effect you want.

Receive
All parameters settable same as 'Send'

Screen-driver
Atari
The standard 24x40 Atari screen driver. This mode does its output to the internal E: device. This isn't very useful for complicated things, but is supplied in case kermit's running someplace where there's not enough memory to do anything better. (Besides, I had to have all the code for it lying aound for other reasons, so why not?)

40-column
A 24x80 screen, using the character CTIA mode. Since
that mode only allows 40 visible columns, the screen
is pannable left to right, allowing any 40-column
chunk to be displayed. The terminal code will attempt
to keep the cursor visible by panning around while
output is happening. You can also pan manually using
the Start and Select keys. In this mode, reverse- vi-
deo output works, but none of the other highlighting
types.

80-column
A 24x80 screen, using the hi-res (320 bits/raster)
graphics CTIA mode. In this mode, both reverse video
and underlining are supported. This is the default
setting for screen mode.

Terminal-emulation
Vt100, Vt52, None
Sets the terminal emulation mode to the specified va-
lue. The default is Vt100.

Show
any of the same keywords as 'Set', or 'All'
Display the value(s) of the specified thing(s). 'All'
displays the values of everything in sight.

Status
Dump various goodies about the last file transfer; characters
in, out, naks, timeouts etc.

Directory [<filespec>]
Display a directory list from the default drive. <filespec>
is optional, if omitted, it defaults to "*.*".

Rename <from-filespec> <to-filespec>
Does a rename operation on files on the default drive. Either
filespec may be wildcarded, in which case the rename operation
happens according to the rules described in the ATARI OS FMS
documentation.

Erase <filespec>
Erases files on the default drive. Filespec may be wild-
carded, in which case the erase operation happens according to
the rules described in the ATARI OS FMS documentation.

Save
Dump Kermit-65 parameters such as screen settings, send/re-
ceive parameters, etc to an init file "KERMIT.INI" on the
default disk.

Restore
Read parameters from "KERMIT.INI" back into the running
Kermit-65.

Help
Gives a summary of the above command list.

Other interesting things about terminal modes:

Depending on what terminal you're using, there are several things
which may be of interest. In 40 or 80 column modes, there's a
status line under the 24 data lines. It displays what special
keys are active, and the status of the comm port. In 40 column
mode, Start pans the screen right, and Select pans left. In both
40 and 80 col modes, Option is used to get the kermit's attention.
In Atari mode, c-Y is used instead.
Once you have kermit's attention, it wants a character; one of:

C Break the connection
B Send a break (approx 1/4 sec)
S Display status

Function keys:

Kermit-65 can generate function key sequences ala VT100. The cur-
rent function key bindings are as follows: (c-sh- means
control-shift...)
c-sh-0..c-sh-9 keypad 0 thru 9
c-sh-. keypad dot
c-sh-backspace keypad minus
c-sh-, keypad comma
c-sh-return Enter
c-sh-q..c-sh-r PF1..PF4
c-sh-- Up arrow
c-sh-= Down arrow
c-sh-< Left arrow
c-sh-> Right arrow

Other key bindings for things not on the Atari keyboard:
sh-< { (left brace)
sh-> } (right brace)
sh-backspace ~ (tilde)
c-sh-backspace, or c-7 ` (backquote)

Kermit-65 Manual and bug list Page 9

These key bindings aren't quite what I had in mind, but the OS rom
won't let me get at all the control-shift keypresses, so they'll
have to do for now. I encourage any feedback about how these
feel. I've been using them for a while now, and they don't seem
as bad as I expected. In particular, they work passably well when
using EDT (I'm typing this document with it), which I think is an
indication that they're useable, as it's a real keypad hog.

Other special keys:

The Atari key (/|\ on 800 vintage dinosaurs like mine, |/| on newer 800XL vintage equipment) behaves in a special fashion when using Kermit-65. It toggles a flag that causes input from the comm port to be held up, rather than processed as soon as possible. This is useful for causing the screen to hold up temporarily when in terminal mode. If flow control is enabled, it behaves in the expected fashion; it'll tell the other side to shut up until you press the Atari key again, to let pending input be processed again.

The status line:

When in 40-column or 80-column terminal modes, there's a 25th line below the usual 24 lines of terminal screen. This is the status line. It will look something like this:

K65: Option + o v Rs ok

There are several interesting things displayed here: At the left side, after "K65", is a list of which special keys (option, select, start) are active at the moment. If you press Option, this will change to a prompt for the special characters that can follow Option. In column 22 ('+', above) will appear '+' or '-', or space. This indicator shows you the state of the flow-control logic; + means incoming traffic is enabled, - means it's disabled. Note that it when flow-control is turned on (see commands, above) this flag will toggle back and forth between + and - as the flow-control logic does its thing. If flow-control is turned off, it will just sit on + all the time. Column 24 ('o' above) will contain a blot if comm-port reading is suspended, space otherwise. In column 26, ('v') above, is the caps lock indicator. It will display an up-arrow if caps are locked, or a down-arrow if not. In column 32 is a message describing the last known state of the comm port.

Com port handling:

In its current configuration, Kermit-65 expects to talk thru an Atari 850. In principal, that ought not to be a restriction, but I (JRD) only have an 850 to test with, and don't know what requirements there are for other devices. I've tried to be scrupulous about sticking to the documented interfaces to things, however, so I'd expect any driver that adheres to the spec to work.

The port's opened and closed a lot; you'll hear it, as I've left the 'noisy bus' option turned on. It uses page 6 ($600) as an IO buffer. Since that's only 256 bytes, there's the possibility of overruns at high baud rates. When flow-control's on, Kermit will attempt to shut off the other side when it sees more than 50 bytes

pending; it will turn it back on when there's less than 10.

As of this writing, Kermit-65 has been out in the field for a while, and seems to work ok with things other than 850s. One word of caution; I've gotten some feedback to the effect that the default timeout values I chose are too short for reliable operation at low baud rates. I've decided not to change the defaults, as you can easily change them in your KERMIT.INI file, and because most folks seem to have access to 1200 bps modems and things these days. However, if you're running at 300 bps and seeing reliability problems, try pushing the timeouts up to say 15 sec or so.

Other ramblings:

Version 3.3 loads at $2D20, and uses up thru about $B000. That means it'll only run on 48K machines. It appears to run fine on XL and XE equipment, but most of my testing has been on an 800, so there may be some problems. BTW, that load address was chosen because the latest version of DOS XL for Indus GT's uses up thru $2D14 when it's configured for two drives, and the 850 driver is loaded. Older versions of DOS XL take up less memory, as does DOS. I don't know what the requirements are for things like Spartados. If anyone comes up with a conflict, let me know, and I'll assemble you a version that's org'ed somewhere else.

On XLs and XEs, kermit-65 will require that the machine be booted with BASIC disabled, as it's not yet bright enough to detect that that's where it is and map out the cart. (if anyone knows how to do that, and feels like saving me some work...) Kermit-65 is available in 'bare' form, or with an autoloader for the 850 driver prepended to it. The bare version requires that you load whatever rs232 driver you're going to use first, then run kermit. The autoloader equipped version does that for you.

For those of you who have YAU (posted separately) the byte count and checksum values for KERMIT.COM and KERMITNR.COM respectively are 24622, #x5F17; and 24408, #x1560.

Credits

I blew it when distributing the first version of this document, and forgot to include this section. Mea culpa.

Many thanks to my beta testers, in particular Marshall Abrams, for his patience in dealing with initial versions of this thing, and for aid in making this document clearer. Thanks also to John Sangster for helping nail down my obscure terminal emulator bugs, and miscellaneous kibutzing. (Sorry John, I still haven't gotten in the key defining util. Maybe next version).

Kermit-65 Manual and bug list Page 13

Bugs and misfeatures:

There's no way to set the comm port to other than R1:. Does anyone care?

The help processor doesn't deal properly with upper-case, and thinks there are no completions.

Vt100 mode is missing still missing insert/delete character.

Blinking fields, bright fields, double-high, double-wide, and 132-col mode are not supported. (Reverse vid and underline are)

There's currently no way to set the screen colors.

It's possible to confuse yourself by hitting c-1 in terminal mode, as my screen drivers ignore it, but Atari's doesn't. You're fine until you break the connection, then everything appears to wedge up.

Flow control for the incoming side of the connection isn't implemented. This can cause problems when trying to send at high baud rates to a host that's got a stupid serial driver, or a small typeahead buffer.

The part of the command parser that deals with pathnames is completely bankrupt (that's what I get for using old code), and doesn't work properly unless it's told that a null pathname is legal. The result of all this is that when entering pathnames and asking for help before entering any data, it will tell you "input file spec or confirm with <cr>". Pay no attention to the man behind the curtain; you really do have to put a pathname in there for anything to happen.

Kermit-65 Manual and bug list Page 14

Bugs fixed for v 3.1

Save and Restore now actually do something, instead of being effectively no-ops.

Rename and Erase commands are now implemented. This means that virtually all file operations one cares about (while up/downloading) can be done without leaving Kermit.

File-warning mode has been fixed so that it really does something useful, instead of just bitching about the file conflict.

The pathname parsing substrate has been installed, so that defaulting and merging can be done in a reasonable fashion, instead of by ad hoc kludgery.

The screen hacking code has been cleaned up a good bit, so as not to be continually clearing the screen when doing transfers.

Logging code has been added to tell the user what files are being sent and received.

Status and help commands in terminal mode are now working.

The directory command now takes an optional filespec parameter.

Bugs fixed for v 3.2

Binary mode now works again. (Sheesh!)

Rename and Erase routines now make sure the comm port's closed before attempting to hack the disk.

The user interface has been cleaned up some; all numeric values other than character codes and some debugging info is now displayed and entered in decimal, rather than hex.

Bugs fixed for v 3.3

Fixed a dumb bug in terminal code that caused graphics mode to be entered at unexpected times.

Kermit-65 Manual and bug list Page 15

Fixed file reading code so as not to get confused and generate an extra byte when running under non-standard things like SpartaDos.

Cleaned up Directory code; using new pathname-mapping substrate.

Added support for wildcarded pathnames in Send code.

Fixed packet-dumping debug code to not mask off top bit of char, and quote everything to keep from interpreting screen hacking chars.

Fixed init code to look for an init file on D1, and read it if found.

Fixed flow control code so as not to wedge up unexpectedly.

Re-enabled the suspend-input capability, using the Atari (/|\) key.

Break (Option-B) in terminal mode has been fixed.

Cleaned up the font used in 80-col mode.

Removed Speedscript file type, as Speedscript apparently just uses plain vanilla text files. Changed default file type to Atascii.

Added caps lock functionality, similar to standard Atari kbd driver.

Fixed a bug in terminal mode that was trashing the stack.

Kermit-65 Manual and bug list Page 16

The Kermit Protocol

The following a brief description of the Kermit file protocol, excerpted from one of the many documents kicking around. If you already know what it is, or don't care, skip this section.

The Kermit protocol allows many (if not most) types of computer systems to effect, at minimum, error free file transfer with other systems and microcomputers over asynchronous lines.

Introduction

With the widespread use of personal computers the need for file exchange between systems has become of foremost concern among users and managers alike. There are many commercial products available which meet this need, some of which may offer more advanced functions such as transparent record oriented file access. Networks that do this, such as DECnet, can be expensive, and if your computer or microcomputer is not on the network your needs won't be met. Transfer of files with removable disks can work, but generally only when the computers are of the same type, it's not very useful when the systems are removed in location. Rarely will a larger mini or supermini be able to read a microcomputer's disk.

A more realistic approach, from both cost and convenience, is to find a way to use ordinary telecommunications and/or in-house PBX systems to connect computers and microcomputers together. If a local connection using a PBX or front end switch is not available, there is always dialup access with standard 103/212 modems. Data can be transferred with very simple methods, such as TYPING a file on one system and capturing it on the other system, but this gives no protection from noise and overrun of data. It is not very user friendly either. What is really needed is a protocol to accomplish file transfer reliably and efficiently.

The first obvious use of any program or protocol designed to accomplish file transfer is to be able to provide the ability to support file uploads and downloads from minis and superminis such as the VAX and PDP-11 to remote personal computers, such as the Atari 800. It should also be widely available for many different micros and mainframes. File transfer from micro to micro, as well as from a larger central host, should be possible. The command interface should be easy to learn, and require no intervention from a central site operator or other user. The many implementations of Kermit follow these lines, and all versions allow some form of transfer in either direction. More advanced versions,

such as those found on the PDP-11, DEC10/20 and VAX, offer what is known as server operation, which allow the remote (connected) Kermit system to completely control the file exchanges from their system. Since as of this writing (October 9, 1985) there are

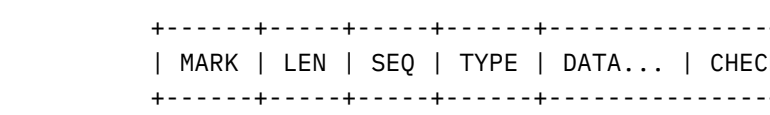
available over 160 versions of Kermit available for numerous micro, mini and mainframe configurations, Kermit addresses this need quite well.

While the primary use of Kermit will likely be to support file transfer from microcomputer to mini/supermini and mainframe connections, there are many uses for Kermit for connections from mini to mini and so on.

The Kermit protocol

The Kermit protocol is designed to operate over normal asynchronous terminal lines. All data and commands are transferred with a packet oriented protocol, basically consisting of a start of packet character (normally SOH), followed by length, control, data and checksum fields. Communication is half duplex, in that for every packet sent, the sender must wait for either an acknowledgement packet (ACK) or a negative acknowledgement packet (NAK). Transmission is in ascii, with no requirements for the transmission of eight bit characters or control characters other than control-A for marking the start of a packet. All 'control' characters imbedded in the data are prefixed to convert them to printable characters, the same applying to eight bit characters if required by the characteristics of the line. Since there are many different implementations of Kermit, the protocol provides a mechanism by which the capabilities of two connected Kermits can be negotiated to allow for differences in the level of protocol support. Examples of protocol features that not all Kermits understand include data compression and transfer of file attributes.

The packet format is



where all fields consist of ASCII characters, and the char function converts a number in the range 0-94 (10) to a printable ASCII character by adding 32 (10). The MARK, LEN, SEQ and TYPE fields are one byte, the DATA field is variable in size, and the CHECK field is one to three bytes in size.
The MARK (normally control A) signifies the start of a packet. The length field tells how long the rest of the packet is. The SEQ field is used to insure synchronization used to detect lost or

duplicate packets. The SEQ number wraps around every 64 packets due to the need to encode it as a printable ascii character in the range 32 (10) to 126 (10). The TYPE field specifies whether the packet is a DATA or CONTROL packet. The DATA section is used for the actual transfer of data or informative messages from a Kermit server, this field can be up to 90 characters in length. Any

character whose low seven bits fall in the range of 0 to 37 (8), ie, char and 177 (8) is less than 40 (8), will have the value 100 (8) exclusive or'ed (xor'ed) with itself and be prefixed by a shift character, '#'. Other shift characters may be use for eight bit characters if the line characteristics require such. Data compression may also occur in the data field, this is done with yet another shift code and byte count sequence. The CHECK field is a checksum, either a one character, two character or three character CRC check; the sender computes it and the receiver must compute it and compare. A checksum mismatch will result in the receiver sending a NAK packet (negative acknowledgment) which directs the sender to resend the NAK'ed packet. The packet may be following by a terminator (likely an ascii 13). This terminator is NOT part of the protocol and is sent only to tell the receiver that a 'line' is present. Not all Kermit implementations require this; all Kermits will discard data outside of a packet in any event.

Error detection and recovery is by checksum, as noted, and by packet read timeouts. If the packet should be corrupted the checksum will be incorrect, the receiver will NAK the packet. If an expected packet never arrives within the timeout period, or if the received packet is not the expected one (as determined by the SEQ field) the packet will also be NAK'ed. There are limits as to how many times an expected packet will be NAK'ed without aborting the current operation.

Packet types

D Data
Y Acknowledgement (ACK), test may be in DATA field
N Negative Acknowledgement (NAK)
S Send initiate (Send-Init)
R Receive Initiate
B Break (EOT, end of transmission)
F File name header
Z End of file (EOF, end of current file)
E Error packet, text may be present in DATA field
G Generic SERVER command. The first character in the
data field will be a command to a server, arguments
may follow that character.
I Login, user and password follow in data field
C CWD, change working or default directory.

L Bye, Logout server
F Finish, Exit server, but do not log out
E Erase, delete files on server system
D Directory query
U Disk space usage query
T Type a file onto local kermit

R Rename file(s) on server system
K Copy file(s) on server system
W Who's logged in, as in sho sys, sy/s, dev tt
M Send a terminal message to a user
H Help, the server responds with commands it can do
Q Server status query
P Program, run a program
J Journal
V Variable, alter a Kermit setting

C Execute host command. The host command follows in
the data field.

Note that some of the generic server commands, as well as the C packet, may not be feasible for a given environment. For instance, the REMOTE LOGIN command, which sends the generic I command to the server, can only be done under systems that allow you to dial up and start a Kermit without logging in; the generic U command (disk space) is meaningless under some systems (like RSX) unless one wants the free space on the entire volume. No Kermit server will abort on receiving a packet it can't execute, it will simply send an error packet with an informative message saying it can't process the requested function.

An example of a Kermit-65 kermit telling a PRO Kermit-11 server to expect a file follows. The Kermit-65 command was "Send foo.txt"

(0)Atari sends: * S~# @-#Y(
(0)Pro sends: 0 Y~* @-#Y1~* ~T
(1)Atari sends: *!FFOO.TXTE
(1)Pro sends: #!Y?
(2)Atari sends: S"DThis is a test file#M#J
containing two lines.#M#JU
(2)Pro sends: #"Y@
(3)Atari sends: ##ZB
(3)Pro sends: ##YA
(4)Atari sends: #$B+
(4)Pro sends: #$YB

In packet zero, the Kermits exchanged information regarding their capabilities. The Atari sent an 'S' packet with the data for its

maximum packet length, default time out, number of pad characters to follow a packet (none, hence the space), use a null for padding, end of line terminator (a CR + 32), the prefix character for control characters, and a 'YES' to say the it can prefix eight bit characters with the default. It doesn't send any of the extension fields, like indicators for multi-byte CRCs, file header info etc. In packet 1, the Atari sends the filename the Pro should use for the file it creates. The Pro then sends the acknowledgement. In

packet three, the Atari sends the first (and only for this file) packet of data. Note that the sequence #M#J is a carriage return/line feed sequence with 100 (8) xored into each character. The '#' character informs the other Kermit that it must xor the next character with 100 (8). In packet three the Atari sends an EOF packet, the Pro acks it. In packet four, the Atari sends a break packet which tell the Pro that no more files (of a possibly wildcard group) are coming and the Pro Kermit acks the break packet. The Pro kermit then enters the server idle state. More specific information regarding Kermit packets and state transitions can be found in the references listed at the end of the article.

Future directions

With the advent of packet switched networks and satellite communications the Kermit protocol will likely be extended to increase efficiency over such links. The main problem is the half duplex nature of Kermit, the packet acknowledgements can take up to several seconds in transit thus drastically reducing the throughput. There are several possibilities under discussion and a standard should be appearing shortly.

Summary

With the knowledge that there are Kermit implementations for most personal computers in use it becomes apparent that the Kermit standard is well worth looking in to.

(End of protocol description)

For more documentation on what Kermit protocol is all about, see the extensive doc available from the Kermit folks at CU20B.ARPA.

697. Re: 1050 disk format

Newsgroup: comp.sys.atari.8bit
Date: 1987-11-11 17:15:41 UTC
From: hans@umd5.umd.edu
Message-ID: <2028@umd5.umd.edu>
Source record: 117401

The 1050 disk drive (as all Atari drives) uses industry standard (or is it IBM standard) Floppy disk format (except that the index hole is not used). In single density FM encoding is used, in double (or enhanced) density MFM encoding is used.

FM encoding records a transition in the middle of each bit cell, and an additional transition between equal bits.
MFM encoding records a transition in the middle of bit cells containing a one bit, and additional transitions between bit cells which both contain zero bits.
Thus transitions are one-half or one bit cell apart in FM mode; and one, one-and-a-half, or two bit cells apart in MFM mode. Note: Since the bit density is twice as high in MFM mode, the actual minimum and maximum spacing between transitions is the same in both modes.

The lowest density of recorded transitions in either mode happens for alternating 0 and 1 bits.
The highest density of transitions in either mode occurs for sequences of all zero bits or all one bits.
The intermediate transition density in MFM mode occurs for sequences of the form 001001001 etc.

A good test pattern probably should contain some of all recording densities. IBM uses data bytes of E5 to fill empty sectors in FM mode, which qualifies on that count. Similarly the pattern 6D B6 DB which was suggested alternates between high and low density transitions in MFM mode. I would think, however, that a good MFM test pattern should also contain a good supply of medium-density signals, to verify that the three spacings can be distinguished reliably.

An additional complication you need to know about is the fact that all data bytes are inverted before they are written to disk, and after reading.

698. Re: Disk R/W problem - causes?

Newsgroup: comp.sys.atari.8bit
Date: 1987-11-11 19:07:15 UTC
From: hans@umd5.umd.edu
Message-ID: <2030@umd5.umd.edu>
Source record: 117402

Unfortunately your problem does not sound like one you can fix by cleaning the head. If you can read old disks, but newly written ones become unreadable and unwritable, I would strongly suspect that your drive speed has drifted out of tolerance. Atari packs things slightly more densely than others, and as a result drive speed is more critical.
If your drive has speeded up, writing a sector may cause the sector id field of the next physical sector to be trashed. The next physical sector usually is 2 logical sectors beyond the current one. (Sectors are arranged in the sequence 1,3,5,...,15,17,2,4,6,...,14,16,18 -- at least on standard Atari drives).
This may also explain why lower sectors work better: The disk may be slowed down more when the head is near the outside of the disk.

Another possibility is that the part of the drive electronics which turns write current on and off is not functioning properly.
This is what I would suspect if writing one sector makes more than it or the next sector on the track unreadable.

There are a few experiments you could do. Get a program which checks your drive speed. If you can find an old disk that
you don't care about, write single sectors and see how much of the track gets trashed. Also try formatting a new disk, and run read-write tests on it.

Good luck, you might need it on this one!

699. John Dunning's Kermit-65

Newsgroup: comp.sys.atari.8bit
Date: 1987-11-11 19:26:59 UTC
From: BILLW@SCORE.STANFORD.EDU
Message-ID: <12349816283.36.BILLW@Score.Stanford.EDU>
Source record: 117403

John Dunning's posinting of KERMIT 65 has been received and may
be FTPed from Score (It is tto large to mail). The file name is
<INFO-ATARI>KERMIT65.NTXT, and it can be retrieved via anonymous
login. The file actually contans several versions (unless I get
around to cleaning it up), and is 340Kbytes long. It is a text
file containg the original mail messages, and should be retrieved
in ASCII mode...

700. Using Kermit65 with either the XM301 or 1030, HELP!

Newsgroup: comp.sys.atari.8bit
Date: 1987-11-12 15:48:00 UTC
From: atariman@bsu-cs.UUCP
Message-ID: <1485@bsu-cs.UUCP>
Source record: 117404

[]
Help!

I recently downloaded the Kermit65 and Kermit65NR. Can anyone tell me how, or if it is possible to use these programs with either the Atari XM301 or 1030 modems? I have both the XM301 and the 1030, but I would prefer to use Kermit with my XM301 if possible. If anyone has been able to do this (with either the XM or 1030), or knows how it can be done, please reply either in E-mail or post the reply.

I think it may be as simple as getting the right handler, but which one is the right one? And where can I get it?

Thanks in advance for any help you can give this peasant XM301/1030 user.

701. Re: ** Kyan Pascal **

Newsgroup: comp.sys.atari.8bit
Date: 1987-11-12 16:30:36 UTC
From: john1233@csd4.milw.wisc.edu.UUCP
Message-ID: <3482@uwmcsd1.UUCP>
Source record: 117305

I wouldn't go out of my way to say Kyan Pascal is great. It has MANY more faults than you give it credit for.

#1 on my mind is speed. I ran the prime number benchmark and here are the results as best as I can remember them.

Action! 5.2 sec.
MMG BASIC compiler 5.3 sec.
Kyan Pascal 8 minutes

I'm not sure of the exact numbers but that is roughly the way it worked out.
Next, your are 100% correct, the Kyan editor stinks!!! enough said about that.

Unless you have a RAMdisk, the Kyan compiler is too hard to work with.
After your are done editing, you must load the compiler. It is huge.
Even with my TRAK drive in turbo mode, it still takes a while. The give it the filename to compiler and to get a soda because it take quite some time to get its job done. If there are errors, you shut off the machine and load the Action! cart for an editor and start over (see above paragraph)

Those are the bad things. Here are the good ones.
Kyan Pascal is a standard Pascal. All normal keywords are implemented.
And (with include files) some extras like graphics commands and random access files.

It has a built in assembler. Not the kind where you must get out your caclulator to figure out BNE or BEQ jumps but it has labels.

It has its runtime file on the disk. You need the file LIB on the D1: to run the program but it can be appended onto the file.

The manual is very good, it is a short tutorial of Pascal.

A little more than my 2 cents worth but it had to be said
Tom

702. Re: ** Kyan Pascal **

Newsgroup: comp.sys.atari.8bit

From: dennett@kodak.UUCP
Message-ID: <1016@kodak.UUCP>
Source record: 117306

A couple of years ago a friend of mine bought this. He was just learning Pascal. He suspected a few bugs in it and gave it to me to look at since I had more knowledge about Pascal. Apparently some of the examples in the manual did not work. Anyway, I played around with it and did find a couple of bugs. If I remember, the WITH construct for records just plain did not work. I had to fully qualify items in records. I think the other bug had something to do with reading and writing files. There was a 255 (or was it 256?) record limit. Does anyone know if these were, in fact, real bugs? If so, were they fixed? I think the version of Kyan Pascal was 1.something.

Source record: 117307

Someone mentioned T:EDIT the other day. I researched my old Analogs
and Compendium and 8-bit Extra, but couldn't find the source. Anyone
have a solid reference or the source I could get?
Walt

704. T:Edit & Xmodem

Newsgroup: comp.sys.atari.8bit
Date: 1987-11-14 14:53:00 UTC
From: V111MFQ6@UBVMS.BITNET.UUCP
Message-ID: <8711142237.AA00863@ucbvax.Berkeley.EDU>
Source record: 117308

I'm not sure what Analog had T:Edit in it, but I have it and a little doc file that just tells what keys do what, if anyone wants it, they can send me mail, and I'll either send it out individually, or if alot of people want it, I'll just send it to info-atari8.

Since Atari 8-bits and most aother computers, including mainframes, use different return characters, there will be a problem. You can do one of two things:

1) Get a program to convert the return characters, I have one that works rather well, if anyone wants it, I'll send it as above.
2) Get Chameleon. In Chameleon, you can specify a file is a text file, and it will convert the return characters, tabs, etc. while it is sending or receiving.

705. More on Atari 65xx CPUs

Newsgroup: comp.sys.atari.8bit
Date: 1987-11-14 23:10:20 UTC
From: ehs@jumbo.dec.com
Message-ID: <1034@jumbo.dec.com>
Source record: 117309

A while back, there was some discussion of the 6502 and the slightly customized versions thereof used in the Atari 8-bitters. I recently got a 65C02 for another project and decided to try it out in my 1982-vintage 800. I also got a copy of Sams' Computerfacts for the 800 on a recent trip to Computer Literacy.

Summary: The 65C02 works just fine in my 800, and both the assembler and debugger in the MAC/65 cartridge support the additional op codes. But apparently not all 800s use a vanilla 6502, so I was lucky.

Details:

The 65C02 I got from Jameco is an NCR 65C02A. I haven't been able to find an NCR data book. I do have a 1984/1985 Synertek data book (their last?) with specs for the 65C02 that I think are equivalent. (I believe that the Rockwell version is somewhat different.) If so, the A version is a 2MHz part. The 6502 that I replaced is a Rockwell 6502B. The latter is a 3MHz part, but specs and experiment say that 2MHz is good enough.

Replacing the chip was fairly easy; anyone not intimidated by removing one 40-pin DIP from a socket and inserting another shouldn't have much trouble. Heed the usual warning and be very careful about unplugging the keyboard; the socket and ribbon cable look fairly easy to damage. Also, expect to see a lot more shielding and a lot more discrete components than typical of more recent home computers; I can see that the 800 must not have been cheap to assemble.

A simple chip swap, without tinkering with the clock, seems to get you the following:
(1) a CPU chip that draws less current (see below).
(2) some new instructions and addressing modes, mostly well chosen to fill annoying gaps in the original, but none revolutionary.
(3) slightly slower decimal mode arithmetic (presumably affecting the ROM floating point routines used by Basic).
I will probably leave the 65C02 installed until I have to open things up again, and I might take advantage of point (2) in some of my own programs, but I still don't consider the 65C02 much of an "upgrade."

The Sams publication was somewhat helpful as a guide to assembly and disassembly. In contrast to the Atari Technical Notes, it includes complete and legible schematics. I was surprised to see that it shows two different versions of the CPU board. The "alternate" version is apparently the original; it corresponds to the schematic in the Technical Notes and matches what I found installed in my machine. Here are brief descriptions:

- The "alternate" board uses a 6502B (Atari # CO14377) plus the following TTL parts:
2 x 74LS244
1 x 7474
1 x 74LS02
Half of the '74 is used to generate the system phi2 signal; the other half is used to synchronize the halt' signal from Antic, generating a signal that suspends the 6502 clock input (gated by the 'LS02), forces Read/Write' to Read (more 'LS02), and disconnects the 6502's address pins from the address bus on the board (the 'LS244s).

- The "standard"(?) board apparently uses a custom 6502 (Atari # CO14806) and a single 'LS244 that simply buffers the 7 low order address bus lines (A0-A6) and system phi2 as they go off the board (always enabled). The CPU appears to use the following non-standard signals:
pin# 35 Halt' input (from Antic)
36 Read/Write' (output, normally pin 34)
37 phi0 (input)
38 ground
39 phi2 (output)
Actually, 37 and 39 agree with a standard 6502, but 39 is not connected on the "alternate" board. I assume that pulling 35 low forces 36 high and tri-states the address pins, but I don't know the timing. The Sams photo shows a part with a Rockwell logo. Rockwell does make several 6502-family devices with built-in tristate capabilities, but these pin uses do not seem to match any of their catalog items.

Replacing the processor in the old version with a 65C02 (or, most likely, a 65C802) is easy. A similar swap on the new version of the board would be a lot more work, presumably requiring duplication of the old circuitry on a daughter board or the like. On the other hand, the new version should draw less power (the '74 and second 'LS244 are not the world's lowest powered chips), so the power savings of CMOS would be less important.

I don't know when the transition from old to new CPU board took place, nor have I investigated the 800 CPU boards available from B&C, etc. I bought my 800 in the summer of 1982, and its 6502 had a 1981 date code. The Sams photos show CPUs with date codes of late 1979 (Synertek) and early 1983 (Rockwell) on the two versions.

I'd appreciate hearing from anyone with more information about this. In particular, is the CPU in the late 800s the same one used on the XLs and XEs? Is there any compatibility with the custom 6502s that have been used in the various Commodore machines?

707. disk drives, question on...

Newsgroup: comp.sys.atari.8bit
Date: 1987-11-15 23:23:44 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8711152323.AA21255@mitre-bedford.ARPA>
Source record: 117311

Can anyone give me an update on disk drives available for the Atari 8-bitters? In particular, is the new Atari 5.25-inch drive available yet, and if so, for what price (and who is selling it)? Is it a Double Sided drive, by the way? Who else makes DS/DD drives (Astra is the only one I have seen)? Does anybody have any strong recommendations pro or con on any of the SS/DD drives out there, e.g. Astra, Percom, Indus? How about recommendations on DD upgrades for 1050s, e.g. U.S. Doubler or Happy? If I want to upgrade a couple of 1050s and also buy one or more new drives, what would be the best, most compatible approach?

What's the best deal going on hard disks for the 8-bitters? Has anybody done a SCSI interface so one can use IBM-PC hard drives?

I trust the answers will be useful to the net at large, so if any answers are sent to me directly, I will summarize them to the net. Thanks for any help anyone can give.

-John Sangster, jhs@mitre-bedford.arpa

|
| I was once told that rubbing alcohol had compounds that did not evaporate.
| I clean my stereo with floppy disk cleaner (:-) because it is the same thing
| as those horrendously expensive bottles they sell in stereo stores, but a lot
| cheaper... (a big bottle costs as much as a little stereo bottle)
+----

Use Isopropyl alcohol, 91% by volume or better. Do NOT use the 75% shit -
it does leave crud on your heads! Qtips leave fibers stuck to things, it
is better to use a special cleaning disk - saturate it with isopropyl,
stick it in the drive, and "format" it :-) Works wonders! (the isopropyl
is also good for the audio stuff)

The better sterio stores have flat, foam tipped swabs with long handles which
are made for cleaning tape drives - they work OK on floppies in a pinch.

Some of the cleaning kits recomend cleaning as often as weekly (shudder)!
I clean the heads about once every 6 months or 6000 miles :-) as needed.
If someone smokes near the drive then you might want to
a) Shoot the smoker -or-
b) Help him/her quit the habit (at least while near the computer) -or-
c) Clean the drive more often (monthly?).

-John

PS. Just a wild guess on the floppy problem, try moving the color monitor
away from the floppy drive - the monitor screws up the electronic signals
on the floppy drive.

The XM301 and the 1030 have have a T: handler built in.
Kermit (and almost all other terminal programs) use the 850 R:
handler.

Well, that answers what handler you need, as to where to get it.
Beats me, try you local users group or a local BBS. I have seen
it available but I never downloaded it because I own an MPP

T:EDIT appeared in the May '87 issue. But no source.
Quote time:
"Listing 1 is the BASIC data used to create TEDIT.COM file.
For those of our readers interested in the assembly language
source code of this program, the listing is available on the
disk version of this magazine, or on the ANALOG Computing
Atari Users' Group SIG on the Delphi network."

That's what ANALOG is doing with most of its assembly lang.
source codes lately. I used to look at these sources and learn to
program in assembly from them. I also used some of their
routines in my programs.
Now I have to pay extra for them on disk or pay to use
Delphi.

ANALOG is slipping! But they will never catch the lack
of quality that Antic now has. Antic is 1 bad publication!

I'm glad I'm not the only one who has given up on Antic and thinks that Analog is slipping. It seems to me that Analog's publication policy is exactly backwards. Object code is for reading by computers; source code is at least potentially interesting to people.

I can't imagine that many readers actually type page after page of numbers into the so-called "machine-language loaders" when disk versions are available at a reasonable price, especially given the risk that the resulting program will be mediocre or worse. On the other hand, I have often gotten ideas and documentation-by-example from the assembly language listings, even when I've had no use for the program itself.

Maybe some letters to the editor or publisher could help to reverse this trend. On the other hand, the appearance of a section devoted to video game machines in the latest issue of Analog seems a bad omen.

Along the same lines, I've noticed that books about the Atari 8-bitters -- good, bad and indifferent -- have almost disappeared from the computer and technical book stores in this area. Also, street prices of current and discontinued models as well as spares seem to be going up. Too bad.

I bought a second hand drive and set it on the TV cart (big 19" color job) to test it. It worked sporadically, and I thought it was a piece of junk. Sometimes it would format a disk, sometimes not. Sometimes it couldn't read its own writing! It was a foot below the bottom of the TV, so I didn't think about magnetic effects. But when I moved the drive to a shelf over the 800 (with my original drive), it worked like a charm and has for about 2-3 years. On the shelf it was about two feet from the TV. Amazing what a little distance can make!

You got them on a rough day. Usually, they're very helpful.

I do not own an MIO, but know many BBS SysOps who do. All of them are
very satisfied with its performance as a hard drive interface. As far
as I understand, the MIO has a "real" SCSI port on it.

Let it be known, however, that software problems prevent usage of the
MIO as an effective printer buffer/interface. IE, don't buy this unit
for your printer, buy it for you hard drive.

The MIO comes in 256K and 1 meg versions. It attaches to the parallel port
on XL's and 130XE's (the latter require an adapter). The driver software is
in ROM in the new parallel device space. A configuration program is
selected during boot or reset by pressing the select button simultaneously.
The MIO features a parallel, serial, and SCSI/SASI port. Serial and
parallel port can be configured for printers, optionally using the available
RAM as spoolers. Any remaining RAM can be configured as RAM disk (with
drivers in software). On repartitioning the RAM the system will initialize
the pseudo disks in SpartaDOS format. If the serial port is not used, it
can function as a regular R: device. Current ROMS seems to have a bug
causing printed output to be lost during spooling while concurrent serial IO
is active. An additional RGB and NTSC port are awaiting an 80 column board
currently on hold (heat problems). Since the RAM has its own refresh and
powers supply, it can be non-volatile (while the AC power lasts). All
drive assignments (serial, RAM, and HD partitions) are interchangable
through the menu (e.g. you can make your old 810 set to be #1 appear as #8).

The SCSI appears to be fairly standard, it definitely supports 4000A and
4070, and should have no problems with SCSI drives like Seagate (I have
heard of people using it). I have used XEBEC 1410A and am now using Adaptec
with no problems.

The MIO is the best things that ever happened to the 130XE (even if it does
have a few bugs). However, you should use a DOS that can handle the larger
drives. I have used all, and find SpartaDOS to be the best by far. ICD's
Flashback backup utiltity is a must (no redundant disk structures, you can
clobber your disk on an unprotected system without too much oif a problem).
Hardback fails on large drives, and does not preserve creation dates
(SpartaDOS has time and date stamping). I am waiting for a field test copy
of ADOS...

The winchesterss are almost as fast as the ramdisk...

->
No, no, no!!! The T: handler in NOT built into the XM301 OR the 1030
modems. The T: handler is usually appended (or pre-pended) to the
modem PROGRAM you are using. Of course, some modem programs have the
handler already incorporated (Express! is a good example). Chameleon gives
you the choice of handlers; you pick from a menu of supported modems and
Chameleon loads up the appropriate handler.

The only terminal programs that use the R: handler are the ones written for
modems connected to a serial interface (R: = RS232??).

I have to disagree somewhat. I read both magazines and type in some of the programs. In the last 1 to 2 years, I have never had a case of a bad program from ANTIC. I can't say that about Analog. Especially bad was their Wheel of Fortune type of game from last December. I typed it in, tried to run it and ran into all kinds of problems. I went to the trouble of debugging it to the extend of my capability. I sent my notes and comments to them and talked to someone at their booth at the Summer CES, all to no avail. I never got a response, nor did I see any kind of correction information in any subsequent issues. I think the version that came on their disk was OK though, because there was one letter from a reader saying what a great program it was. I can guarentee you he didn't type it in from the magazine. In general, Analog's coverage of news in the industry seems to be better though, and they have more reviews.

To the many people who've replied so far to my earlier posting about trouble with MY Percom SS/SD drive, Thank You! I'll summarize to the net soon, when Finals Week is over here at Ball State.

But, as long as you're thinking of answering John S's question above, why not answer this at the same time:

If any of you have a Percom drive, where are you getting maintenance, service, support etc? I've tried to phone Percom Data at both numbers (normal and toll-free) listed in my drive manual, but neither is in service apparently. Am I correct in assuming Percom Data is OUT OF BUSINESS? I'd be especially glad if anyone in Dallas could take a drive past "11220 Page-mill Rd." and SEE if Percom Data is there... (The phone number they give, incidentally, is (214) 340-7081)

Thanks in advance.

Chris Chiesa

> or otherwise maintained since I bought the drive in mid-1983. Can
> anyone offer opinions on the likelihood of this being the cause?

I don't think so. From past experience with many types of disk drives (mostly
large mainframe types) and tinkering with my 8-bit drives when they bite the
big one. I have found that this type of error is usually indicative of the
carriage-way being out of alignment. A simple head out of alignment symptom
will give you problems on all or most of the tracks at one time with the
key symptom being that the drive will format, write and read itself just fine,
which makes sense since the heads are in the same place for writing as reading
even if that is the wrong place,but a disk written on a properly aligned drive
(as is the case with store bought programs) can not be read on the misaligned
drive.Also try formatting and writing all sectors on the drive in question
and then trying to read what it wrote on a known good drive.This may or may
not work since a drives alignment is only as good as the alignment disk used.
And these can vary by more that you could believe.
This is easily corrected if you happen to have a scope and alignment
disk and diagnostic cartridge(which I do:-)).
But your case is a little more complicated. It appears that the heads are
not tracking in a perfectly straight line. So at track 0 the heads are in
line but as they move closer to the spindle they angle either to the write
or left and eventually are out of alignment.
I don't know if the drive mechanism you are using has an adjustment for
the carriage-way or if you could get someone with the right equipment to
do it. You need a calibrated micrometer and a way to attach it to the
carriage-way and some way to adjust it. I think it would be cheaper to
just get another drive or head assembly.
But before you trash the drive completely you could try to adjust the
head alignment slightly in one direction and then test it. If it still
doesn't work or if it is worse then try the other direction. Since the
alignment has a margin in it for compatibility (slop) with other drives moving

the alignment slightly like this may be able to compensate for the carriage-way problem. I have aligned my sisters drive like this in the past before I aquired the proper equipment and it is still working today. I formatted a disk on a known good compatible drive and then ran a program that tested disk speed constantly while I moved the alignment screw until the disk would read. The procedure took some trial and error and I actually ended up moving the heads much farther than I thought I would have to. After the drive will pass the speed test then try and test all the sectors on the known good disk. If it works your all set if not try it again if you have the patience. This procedure took me about 45 minutes (and I do it for a living). The final test will be to format a disk on the adjusted drive and then test all the sectors on your known good drive. GOOD LUCK.
I hope I wasn't to long winded on this one.

Source record: 117327

I just saw the "Insight Atari" column in the latest COMPUTE!, and it contains a glowing review of the new Atari SF551 (hope I got that right) disk drive. Bill Wilkinson is working on the new ADOS for Atari, and says it is not quite ready yet, but the drive is apparently "real", at least in prototype form. It IS both Double Sided and Double Density, and is said to be priced at "under $200". Apparently it DOES support the Percom standard, and is very flexible in terms of being programmable. In DS/DD mode, that is 360K bytes per disk -- not bad! It'll also read older SS/SD and SS/DD disks without problems, being able to figure out the format for itself! (Well, maybe with a little software help!) And it's FAST, especially when the disk is formatted under ADOS to take advantage of the drive's capabilities.

Wilkinson had nothing but praise for this product. I think I've made up my mind what floppy drive to buy, as soon as it appears on the shelves!

Message-ID: <8711190814.AA15522@ucbvax.Berkeley.EDU>
Source record: 117328

In response to Dragos Ruiu's posting about disk drive speed checking, the method described to check for an accurately adjusted disk speed:

> If you physically remove the drive you will notice it should have
> a ring of alternating black and white spots on the flywheel. If you watch this
> wheel under a fluorescent lamp (You must be in a country with 60Hz power) the
> spots should stay still. If they don't, your drive is too slow or fast.

does not work on drives designed for the Atari 8-bit computers. This method will accurately detect a drive running at 300 RPM but for some ungodly reason, Atari decided their drives should run at 288 RPM! (Does anyone know WHY?!)

There are several programs available to test the disk speed but all pretty much do it the same way:

1) read sector 1 repeatedly recording the time it takes between successive reads
2) average these times and scale them into an RPM

Obviously to be fast enough, this must be done in ML and I am not equipped to post any of the many drive testers I have.

With regard to Stan's original problem, I might also comment about the possibilities of alignment problems. If the drive has not been serviced at all in many years, the alignment might have drifted. However, this should only show up when trying to read old disks, not ones just written. It can destroy an otherwise good disk that has been recently written to and does appear to be a variable problem at different tracks since when a tech aligns a drive, he tests it on track 1 and 40 and then in the middle (around track 20, I think.) For this problem, short of an oscilloscope, there is no way to detect or repair it at home.

o ANALOG is slipping! But they will never catch the lack
o of quality that Antic now has. Antic is 1 bad publication!

Analog sure will give Antic a run for the money in bad customer satisfaction. After buying Analog and Antic on the newsstands for a year I decided Analog was the better of the 2 magazines. I subscribed last December. I have spent the last year writting letters to Analog and making phone calls to Robin Levitsky trying to get my subscription straightened out. I have yet to get a single issue through normal subscription channels. I ususally wait 2 or 3 months and realize that the mag just isn't going to show up and then give Robin a call and a couple of weeks later my back issues show up. All my letters get no answers. I have even sent a letter to the editors and I still have no answer. My magazines show up months late and there is no response from the editor even attempting to explain why.

Analog's customer satisfaction rating is about as low as you can go. You can bet that when they mail my renewal card to me I will ignore it also.

The T: handler is built in to the 1030, and some terminal programs do load the handler from the modem (such as older versions of 1030 Express!). You hear basically the same whine from the 1030 when the T: handler is being loaded as when the R: handler is being loaded from the 850. The T: handler (or any other handler for that matter) is not built into the XM301 though.

To use the built in terminal software (ModemLink(?)), all you have to do is boot the computer without any other devices on (except for the printer, if you use it with Modemlink) and without BASIC. The built in software on the 1030 is not very good (to say the least). No file transfer what so ever. Just, basically, a dumb terminal.

One thing I have to say in its (Modemlink) defense, it is good if you just want something to log-on quickly.

Not so, the 1030 modem does have the T: handler in ROM in the modem
along with a built in terminal program. I don't believe that the XM301 has
this. I believe there was some code floating around that would pull the
handler out of the 1030.

Sorry, wrong again. The T: handler _is_ actually loaded from the
ROMs of both the XM301 and the 1030. In fact, this is why you can use the
1030 with _no_ software of any type -- it has its very own terminal emulator
built in. If you have this as your only device on the SIO, the OS will
automatically dump you into the most brain dead terminal program known to man.

A program has to call this routine, however (like 1030 Express!)
That is the high-speed squeal you hear when booting Express--it is the
sound of data coming over the SIO (you know the annoying beeping sound that
you get when data is read/wrote from disk or tape?) Same thing.

Keywords:St for sale.

Hi all, due to personal projects, and recent MONEY IN HAND!, I am moving up to a Mega2. My 1040ST and monochrome monitor are up for sale. The 1040 is about 4 months old and in perfect condition, the monitor belongs to the Atari shop that I work for part time. The owner has allowed me to sell it with the 1040ST so that I can keep my colour monitor, at cost price, so this means the monitor comes with full warranty! I will also be including some extras like a new parr. printer cable, anti static dust cover and some software(yes orginals). All I can say is that this gear is in perfect condition. I would like to get around $1100.00 or so for the system and extras(Can. dollars). If interested call me at 1-(902)-542-2312 or 1-(902)-466-5345. Or just reply to this message. Do yourself a favor and move up into the world of the ST, I promise you will not be sorry.

Yes. There is a special 800-only version.

>
> (b) on an XL/XE under SpartaDOS or DOS-XL or any other
> DOS that uses portions of the RAM under ROM?
Perhaps the 800 version will, but the XL version won't.

To: Info-Atari8@score.stanford.edu

A while ago, I posted an upgraded, bug-fixed etc version of Kermit-65.
I haven't seen it appear in the archives, nor have I seen any mail about
it. Does anyone know what happened? Did it disappear into hyperspace?
I'll repost it if so.

Second thing: I'm whipping up a new assembler for use in the C compiler
project, and was wondering what sort of macro syntax anyone prefers?
In particular, what does MAC/65 do? I gather from reading mail that a
number of folk like that one. Any other favorites? Any particular
kinds of macro capabilities in demand?

Finally, in digging back thru old mail, I discovered a rumor that
someone was going to come up with a relocatable object format. I
haven't seen anything about it since; does anyone have any info about
such a thing? If not, I'll finish my own design and use that.

Thanks for any feedback.

Subject: 1050 disk format

I am writing an exerciser for my (unmodified) Atari 1050 disk drive,
and I would like to know what the "worst cast" pattern is that I should
write to the disk to test for bad media.

For the uninitiated, the worst case pattern is like alternating ones
and zeroes, except that the particular method of encoding the ones and
zeroes on the disk may mean that a different pattern is actually the
"worst" case. Thus, even if you don't know which pattern is worst you
could help me if you could tell me how ones and zeroes are physically
stored on the disk. Thanks in advance.

735. I/O Port expandtion module

Newsgroup: comp.sys.atari.8bit
Date: 1987-11-20 15:15:13 UTC
From: Mead.WBST311@XEROX.COM
Message-ID: <871120-071531-1382@Xerox>
Source record: 117339

I have an Atari 800 XL computer at home collecting dust ,I am thinking about using a computer at work to run a power supply test and I thought about using an Atari 130 XE instead of Comadoore 64 . The reason for think
ing about this is the Atari is less expensive it is some what compatable with my computer at home and I can communicate via a modem from home also.
I am not all that familar with the accessability of I/O Port expandtion of either computer . Imformation in this area would help also is Basic on the XL
machine much different from the XE machine and the same question holds for the DOS systems too. My XL machine has DOS 2.5 which replaced DOS 3.0.
I know someone who did the same type of testing of a power supply but he did it with a Apple computer but I would like to a avoid the cost factor so I can gain my Managers approval much easier . Also I have a question for Rochester Xerox User where are the locations of the local distributers of Atari computers . I bought my computer from K-Mart when they were on sale because they discontinued the sale of Atari equipment. Any help would be appreciated and please excuse me for any misspelled words I do not have any more time to check for spelling.

Thanks again, Bob Mead

I don't know if the following company is the same under a different name but it is in the same part of the country.

Computer Serviceland
14506-B Lee Rd.
Chantilly, VA 22021
(703)-631-4949

They advertise Percom drives at very good prices (which I won't mention in deference to our ARPAnet friends).

They do service work on Percom drives and they have a ROM upgrade kit to correct a timing problem when they are used with XL/XE series of Atari computers. The price is quite reasonable (it is the fourth bill in ascending order of US currency starting with $1, $5, etc). I have recommended to others via Email, but I don't know if anyone has actually tried them.

>modems connected to a serial interface (R: = RS232??).
>

Ok. Now for some facts. The XM301 and 1030 modems do indeed have a
built in T: handler. In fact, it is described in some great detail in
Antic magazine. I'm not sure what issue it is in, but the article is
written by the same guy who wrote the Hometerm program.

Sending commands to the T: device driver is much different than sending
commands to the R: device driver. The R: driver responds to XIO
commands from basic, or their equivilent CIO calls from assembly. The
T: handler is accessed by setting memory location 7 to non-zero, and then
sending ESC sequences. Memory location 7 is then set to zero, and the
ESC sequences are just sent through to the modem.

There are many device drivers for the 1030 and XM301 modems that act
like T: and R: drivers, however, and they are often pre-pended to
terminal programs to supply the required device driver. I have seen a T:
handler that uses XIO calls instead of using ESC sequences for control
of the modem. I have also seen an R: driver for the 1030 and XM301 that
implement the stantard XIO calls of the 850 R: driver. This driver also
implements additional XIO calls to support dialing, going on and off
line, and other various modem functions. This is the device driver that
I am using to run the Omnicom terminal program posted to the net a while
ago.

Now, to use Kermit 65 with the 1030 or XM301, one of two things must be
done. The first is to find an R: driver for the 1030 and XM301 that
emulates the Hayes command set. I have heard of a rumor that such a
driver exists, but I have never seen it. If someone has one, please
post it to the net, as the rest of us would appreciate it. The second
possibility is to teach Kermit 65 how to dial the 1030 and XM301 modems
if present. This is not that hard to do, provided source code is
available. I will send John R. Dunning info on how to do this as soon
as I am able to write it all down legibly. Maybe he will release a 3rd
version of Kermit 65 then. :-)

Well, I have gone on long enough, and I haven't even mentioned the MPP modem and the similiar problems that it has. I will have an MPP to play with during Christmas break, and if I find anything interesting, I will post it to the net. Till then.

Kenneth Sumrall
ARPA: sumrall@msudoc.egr.msu.edu
UUCP: ihnp4!msudoc!sumrall

P.S. I would appreciate any and all replies concerning the above, but no flames please, my flame proof suit is at the cleaners. :-)

The easiest way to interface some I/O device to an 800XL is through
the joystick ports. Together they provide 8-bits parallel input/output
through the PIA chip in the computer. The PIA has 16 bits of I/O but
the second 8 are used to bank switch memory.

There are also four pot inputs.
BTW the ports can be configured for x bits input and y bits out.

References:

Mapping the ATARI, Ian Chadwick, compute books
Every ATARI owner MUST get this book, it's the best memory map around.

Bits & Pieces, a column in Analog computing. Get the back issues first,
they have clear data on setting up the ports.

An 8-bit parallel interface for the 800xl, Analog computing. I forget which
issue, but I can find it (probably was from 1985). I believe this was an
interface that provided handshaking and parity checking. Hardware and
software.

Sams Computerfacts, of course.
I have neither their repair manuals or their programming manual, but
people keep referring me to these. Check electronics stores for these
(not radio shaft).

I am thinking about applying the Archieve compression to compress boot disks. Currently, there are so many programs that transform boot disks into files, such as Scrunch, Shrink, and Masher. They all claim to reduce the size of the transformed disks to minimum. I believe none of them will be able to compete with the Archieve compression, so I propose that we write a program using the Archieve compression.

Furthermore, I also propose a better version of Archieve file for the Atari. The current version is so slow...

Here is the DOCs and UUE T: handler for the Xm301. I couldn't get
it to work with Kermit65. If someone does, please let me know!

ATARI[R] XM301 MODEM[TM]
TECHNICAL SOFTWARE SPECIFICATIONS

This manual contains the reference
specifications for the software
interfaces used by applications
programs and the Operating System to
control the XM301 Modem.

Contents

Section 1: Description of the XM301
Modem
Interface With Other Products
Family of Products
Reference Documents
Section 2: Logical Requirements for
the XM301 Modem
Man/Machine Interface
The Six Standard Input/Output
Command Interfaces
OPEN
CLOSE
INPUT
OUTPUT
STATUS
Parameters Passed as Data Strings
Error Handling
Buffer Use
Handler/Operating System Interface

SECTION 1
DESCRIPTION OF THE XM301 MODEM

The XM301 Modem is a stand-alone
peripheral which connects to the
ATARI 400[TM]/800[TM], and the
XL[TM]/XE[TM] series with the SIO
interface by means of the serial bus.
The modem connects to the telephone
line by means of the RJ-11C jack.

The modem control software resides in the internal ROM of the 8048 single chip microprocessor. A separate software handler will be disk-based.

Interface With Other Products

The XM301 Modem is an input-output peripheral, and performs no actions without instructions from an applications program.

To use the XM301 Modem from a high-level language, the following types of commands are required:

OPEN
CLOSE
GET (or equivalent READ, INPUT)
PUT (or equivalent PRINT, WRITE)
POKE
PEEK

Family Of Products

The XM301 Modem performs telecommunications functions in conjunction with applications designed specifically for use with the XM301. It is interface compatible with the Telelink II[TM] application. The modem is capable of accepting any commands issued by the Telelink II handler without performing in an irregular fashion or returning the "illegal command" error code.

Reference Documents

ATARI Home Computer System Technical Reference Notes:
Operating System User's Manual
Operating System Source Listing and Hardware Manual

The Technical Reference Notes are available from ATARI Customer Relations, P.O. Box 61657, Sunnyvale, CA 94088. Cost: $29.95 plus $2.50 for shipping. California residents should add appropriate sales tax. Write "Order for Technical Reference Notes" on the outside of the envelope

to speed up the order process.

SECTION 2
LOGICAL REQUIREMENTS FOR THE XM301 MODEM

The handler is provided by an AUTORUN.SYS disk file.

The modem controller, an 8048H microprocessor, is accessed by the handler through the serial I/O channel.

The handler uses RAM for input and output buffers, variables for communicating with the user, and internal variables. Internal variables are in low memory, with one variable (CMCMD) permanently allocated in the Operating System database for use by this handler.

User communication variables are the system IOCBs, the zero page IOCB, and the command flag CMCMD. IOCB use is described in the ATARI Home Computer System Technical Reference Notes, and in Section 2, Handler/Operating System Interface. CMCMD use is described in Section 2, Parameters Passed As Data Strings.

The XM301 handler allocates an input and output buffer where data can be entered between the application and the handler. The output is 64 bytes long; the input buffer is 256 bytes long. There are 2 bytes used for buffer control variables by the handler. Applications use of buffer control bytes is described in Section 2, Buffer Use. The remainder of the buffer area is reserved for the buffers. The use of the buffer area is decided upon by the handler. The application program has no defined way of directly accessing data in this area.

Man/Machine Interface

It is the responsibility of the mass storage media device to contain and load the XM301 handler along with the required applications.

The Six Standard Input/Output Command Interfaces

The applications program accesses the modem handler by calling on CIO, which in turn, calls the handler. There are six I/O calls.

(1) OPEN

An OPEN command must be performed before any other modem operations are allowed. Any of the IOCBs may be used. Aux1 specifies the I/O direction: bit 2 for input; bit 3 for output; both for bidirectional. The directionality applies only to communications data; initialization parameters are passed in either direction after any OPEN command. Aux2 is ignored by the handler.

The device name is "T". The rest of the filename is ignored.

The command flag (CMCMD) is set to zero by the handler during OPEN.

(2) CLOSE

The CLOSE command terminates the I/O procedure and releases the IOCB. Any data waiting in the output buffer is sent first. The buffer area is then relinquished and any input data remaining in the buffer is lost. When the buffer area is empty, the phone is placed on hook.

[System.Reset] produces similar results to the CLOSE command except that the output buffer is not sent. Refer to Section 2, Handler/Operating System Interface, for details.

The modem operation may be suspended without closing the IOCB, allowing the serial bus to continue communicating with other devices.

This operation is described under the appropriate commands in Section 2, Parameters Passed As Data Strings.

(3) INPUT

Any INPUT or GET operation through CIO will result in the modem handler being asked to provide data for the user.

If no data is available, the handler waits for a character. There is no time-out when waiting for received data. This waiting is terminated when either the [Break] or [System.Reset] key is pressed. The waiting is also terminated if the carrier is lost. Error 136 is returned when the carrier is lost.

If data has been received, the Handler stores the characters in the input buffer as the data is received (up to the buffer's capacity). The CIO request for data is then satisfied from this FIFO buffer. (See Section 2, Buffer Use.)

The modem is double-buffered, so the handler has one character time to input each character received.

Communications data is processed for parity and for translation from ASCII to ATASCII. These operations are described under the appropriate commands in Section 2, Parameters Passed As Data Strings.

(4) OUTPUT

Any PRINT or PUT operation to CIO will result in one or more bytes for the handler to hand to the modem.

This data is interpreted either as set-up commands and parameters, or as communications data, as controlled by the command flag byte CMCMD. (See Section 2, Parameters Passed As Data Strings.)

Communications data is processed for translation from ATASCII to ASCII, and then from parity. These operations are described under the appropriate commands in Section 2, Parameters Passed As Data Strings.

Output bytes are received by the handler and placed into the output buffer as fast as the bytes come from CIO. If the FIFO buffer fills, the handler loops other character from CIO until space becomes available in the buffer. There is no time-out when the handler is waiting for buffer space. The looping is broken when either the [Break] or [System.Reset] key is pressed. A loss of carrier also breaks the loop, and returns Error 136.

Any time the buffer contains data, the modem continues to send until the buffer is emptied.

(5) STATUS (Combines with PEEK)

The STATUS command causes the handler to place four bytes of status information in the Operating System status area DVSTAT through DVSTAT+3 (02EA - 02ED). These four bytes contain error and status information from both the modem and from the handler. The application program can then PEEK at these four bytes.

The four bytes contain the following bit-encoded data:

DVSTAT+0: Communications Error Flags

The internal flags corresponding to the status bits in this byte are reset upon STATUS request.

Bit 7: Framing error encountered on received data.

Bit 6: Byte-level overrun encountered. The modem lost one or more characters due to slow interrupt handling. This is caused either by slow reading of data by the

application, or by an incorrectly programmed main CPU.

Bit 5: Parity error encountered on received data.

Bit 4: Received data buffer overflow. The received data buffer overflowed because the applications program did not input data from the buffer in time. If the received buffer has not been supplied, only error bit 6 is set.

Bit 3: Zero (Reserved for expansion).

Bit 2: Zero (Reserved for expansion).

Bit 1: Zero (Reserved for expansion).

Bit 0: Illegal command (recognized by handler). This error applies only to the most recent command. This error is cleared upon acceptance of a legal command.

DVSTAT+1: Modem Status Flags

Bit 7: Carrier detect. 1 when the carrier is present.

Bit 6: Zero (Reserved for expansion).

Bit 5: Loop Test enabled. 1 when Analog Loopback Test is active.

Bit 4: Originate/Answer. Zero = originate, 1 = answer.

Bit 3: Auto-Answer. 1 = enabled, 0 = disabled.

Bit 2: DTMF dialing. 1 for DTMF dialing.
0 for pulse dialing.

Bit 1: Zero (Reserved for expansion)

Bit 0: Off hook. 1 when the phone
is off-hook.
0 when the phone
is on-hook.

DVSTAT+2: All bits set to zero.
(Reserved for expansion).

DVSTAT+3: All bits set to zero.
(Reserved for expansion).

(6) SPECIAL (XIO)

This call is not supported by the handler. The handler returns Error 92 (hex), 146 (decimal), Function Not Supported.

Parameters Passed As Data Strings

Control functions (i.e., setting translation and parity handling, sending a break signal, and dialing the telephone) are handled by passing the commands and parameters to the handler as the output and input data.

There are two types of commands: Those with parameters and those without. Commands start with a two-byte escape saequence output to the modem handler. This escape sequence identifies the start of the command and specifies the command. If the command containsparameter bytes, they are sent immediately following the escape sequence.

In normal operation, the CIO output deals only with communications data. The handler checks the Operating System RAM area command flag byte CMCMD as it receives each output from CIO. (CMCMD is fixed in the Operating System database at location 0007.) If the flag is zero, the handler treats the byte as communications data. If the flag is nonzero, the handler treats the byte as a command.

When the handler is not processing a command, output bytes sent with CMCMD nonzero are checked for a command and

are not transmitted. The handler starts processing a command when: It is not processing a previous command; CMCMD is nonzero; or the output data byte received is ESC (1B hex, 27 decimal). Once a command sequence starts, the handler finishes the sequence regardless of the state of CMCMD. The number of output and input bytes is constant for any given command (except the DIAL command). When the command bytes have been passed, the handler again checks CMCMD with each output byte.

Commands start with two output bytes: [Esc] followed by the command letter; and the commands with output parameters containing those two bytes followed by the parameter.

The handler ensures proper sequencing of commands with output data by emptying the output buffer prior to processing the command. This operation occurs when the command is accepted (i.e., the command letter is accepted). During this output buffer drain, communications input characters are saved in the input buffer.

With both the handler and modem, communications being received are placed in the input buffer even when commands are being processed.

Except with the BREAK command, each command below is completed when the handler returns from accepting the final byte. Execution of a command may result in an error which is returned by the handler to the application when the command completes execution. (See Section 2, Error Handling.)

Illegal commands (command letter not valid) produce Error 84 (hex) 132 (decimal), an invalid command, and are not processed.

The commands are defined as follows:

SET TRANSLATION: (A ASCII, 41 hex, 65 decimal)

Two bytes of parameter follow this command. The first specifies the translation options. The second is the will-not-translate substitution character. Translation always follows parity checking on input, and always precedes parity setting on output. The translation options are interpreted as follows:

Bit 7: Ignored by the modem.

Bit 6: When 1, specifies appending linefeed (0A hex, 10 decimal) whenever a Carriage Return (OD hex, 13 decimal) is transmitted. This bit is ignored if bits 5-4 of this parameter byte are 10 or 11. The Carriage Return character may come either from the untranslated ATASCII graphics character with code OD hex, or from the translation of ATASCII EOL (9B hex, 155 decimal) to CR. This translation option has no effect on input data. The initialization default for this bit is 1.

Bits 5 & 4: When 10 or 11, specifies no translation. This option suppresses bit 6.

When 00, specifies minimal ("light") translation. On input, Carriage Return (0D hex, 13 decimal) is converted to EOL (9B, 155). On output, EOL is converted to CR. Bit 7 of code is cleared in both cases with the exception of EOL (9B, 155).

When 01, specifies major ("heavy") translation. Codes whose interpretations in ATASCII do not correspond to the ASCII interpretation are untranslatable. Codes below Blank (20 hex, 32 decimal) and codes above Vertical Bar (7C hex, 124 decimal) are untranslatable, with the exception of

Carriage Return and EOL. CR and EOL are translated just as in mode 00. On output, untranslatable codes are suppressed and not transmitted. On input, untranslatable codes are converted to the will-not-translate substitution character supplied by the user.

Bits 3 - 0: Ignored by the modem.

SET PARITY: (C ASCII, 43 hex, 67 decimal)

One byte of parameter follows this command.

Bits 7 - 4: Ignored by the modem.

Bits 3 & 2: Specify input parity operation. The input parity operation precedes the translation operation. 00 specifies no parity operation. 01 specifies an odd parity check. 10 specifies even parity checking. Should any parity check fail, the parity error status bit is set. 11 specifies no parity checking. In all but mode 00, the parity bit is cleared after the check. The parity bit is always bit 7 (high-order bit) of the 8-bit form of the character, regardless of transmission byte size. The default for these bits is 00.

Bits 1 & 0: Specify output parity generation. The output parity operation follows the translation. If LF is appended to CR, each is treated separately for parity. 00 specifies even parity. 11 specifies forcing the parity bit to 1. The parity bit is always bit 7 (high-order bit) of the 8-bit form of the character, regardless of transmission byte size. The default for these bits is 00.

END OF COMMANDS: (E ASCII, 45 hex, 69 decimal)

The handler sets the command flag CMCMD to zero when it receives this command. The user has the option of ending command mode either by poking CMCMD to zero or by including this command in the output.

STATUS: (F ASCII, 46 hex, 70 decimal)

Performs the same function as the C10 STATUS call (DVSTAT through DVSTAT+3 shall be filled in the Operating System RAM area). This alternate status call is supplied for high-level languages lacking the C10 STATUS call. No data is returned in the input stream.

SET AUTO-ANSWER: (G ASCII, 47 hex, 71 decimal)

The modem is set in the AUTO-ANSWER Mode. (The default AUTO-ANSWER is disabled.) Once Auto-Answer is enabled, all subsequent incoming phone calls will be considered as computer connections. To disable the Auto-Answer use the [Esc][T] command.

BREAK: (H ASCII, 48 hex, 72 decimal)

A BREAK signal is transmitted. The execution of this command is deferred (control returns immediately and the BREAK is sent for the following 500ms). Output data is buffered until the BREAK finishes.

Since the BREAK transmission proceeds concurrently as control is returned to the caller, another command may be given to the modem handler before the BREAK is completed. Should this happen, the handler finishes the break and transmits any characters being held in the output buffer before executing the new command.

SET ORIGINATE: (I ASCII, 49 hex, 73 decimal)

The modem is set in Originate Mode (the default).

SET ANSWER: (J ASCII, 4A hex, 74 decimal)

The modem is set in Answer Mode.

DIAL DIGITS: (K ASCII, 4B hex, 75 decimal) Used for pulse dialing.

A string of digits to dial follows this command. Each digit is held in one byte. The handler ignores the most significant four bits of each digit byte, and interprets the low-order bits as follows:

0 - 9 Digit to dial, 0 through 9

B End-of digits

C 3-second delay

A,D,E,F, Ignored (reserved for future expansion)

(Note: Digits may be represented in either ATASCII or BCD.)

For pulse dialing, the controller is responsible for inter-digit timing. After dialing each digit, the modem waits the appropriate inter-digit time before accepting the next digit. The controller dials each new digit as instructed to do so.

For DTMF dialing, the handler is responsible for timing and transmission of the DTMF tones by generating them from POKEY and transmitting them into the telephone line.

The end-of-digits characters are required to terminate each DIAL DIGITS command. The handler interprets each character received as a digit for dialing until an XB (hex) character is received. (Note: ATASCII EOL, 9B hex, may be the terminating character.)

It is not required that the user dial a complete telephone number with one use of the DIAL DIGITS command. The user may use more than one DIAL

DIGITS command to dial a phone number. There will be no signal to the modem of the last digit of the complete phone number. The modem assumes each DIAL DIGITS command may be the last, and monitors for the carrier following each command. The modem starts a thirty-second time-out following each end-of-digits command. If neither another DIAL DIGITS command nor carrier is detected in the period, the modem will place the phone on-hook.

In DTMF dialing mode, the computer resident handler passes dial tones directly through the modem, and terminates the dialing sequence with the thirty-second timeout "P" command, causing the wait for carrier detect and subsequent actions (establishing line connect or time-out and going on-hook).

GO OFF-HOOK: (L ASCII, 4C hex, 76 decimal)

The modem takes the phone off-hook. The modem then monitors for the carrier (with thirty-second time-outs.

GO ON-HOOK: (M ASCII, 4D hex, 77 decimal)

The modem places the phone on-hook (the default). This command is used to terminate dialing, or to terminate waiting for the carrier following dialing.

SET PULSE DIALING: (N ASCII, 4E hex, 78 decimal)

The handler communicates dial digits commands to the modem for pulse dialing (the default).

SET TONE DIALING: (O ASCII, 4F hex, 79 decimal)

The handler performs dial digits operations itself by suspending

operation of the modem on the SIO interface, generating the tones using POKEY, resuming operation of the modem, and invoking a thirty-second time-out using the "P" command.

START THIRTY SECOND TIME-OUT: (P ASCII, 50 hex, 80 decimal)

The modem begins a thirty-second time-out for detecting a carrier. This command is used after generating a tone-dialing sequence from the computer. If no carrier is detected within thirty seconds, the modem place the telephone on-hook.

RESET MODEM: (Q ASCII, 51 hex, 81 decimal)

Reinitializes the modem controller code.

ENABLE SOUND: (Ru ASCII, 52 hex, 82 decimal)

Turns sound to T.V. on

DISABLE SOUND: (S ASCII, 53 hex, 83 decimal)

Turns sound to T.V. off. (The default)

DISABLE AUTO-ANSWER: (T ASCII, 54 hex, 84 decimal)

Turns Auto-Answer mode off. (The default)

SET ANALOG LOOP: (W ASCII, 57 hex, 87 decimal)

The Analog Loopback Test is turned on.

This command is used by an application with an appropriate indication to the user as to whether the test has passed or failed.

CLEAR ANALOG LOOP: (X ASCII, 58 hex, 88 decimal)

The Analog Loopback Test is turned off. This is the default state.

RESUME MODEM OPERATION: (Y ASCII, 59 hex, 89 decimal)

Communication with the modem is re-enabled. This command is used in conjunction with the SUSPEND command (see description below) to reallocate the serial bus for communication with the modem. Execution of this command causes CMCMD to set to zero and fills DVSTAT through DVSTAT+3 with current status information.

SUSPEND MODEM OPERATION: (Z ASCII, 5A hex, 90 decimal)

Communication with the modem is disabled. The nature of the serial bus protocol requires that no other device may use the serial bus while the modem is in an active (receiving) state. The SUSPEND command, unlike the CLOSE command, maintains all of the current modem settings (phone stays off-hook) including data which may remain in the user-supplied I/O buffer. Upon execution of this command, the serial bus is relinquished and the application can communicate with other peripherals.

While the modem is in the "suspended" state, only the RESUME MODEM and CIO CLOSE commands are considered valid and processed normally by the handler. All other operations requested of the handler return the CIO error code for invalid command(84 hex, 132 decimal).

Any information received by the modem over the telephone line while the modem is "suspended" will be lost. It is the responsibility of the applications software to guard against this possibility (i.e., by implementing a flow-control protocol).

Error Handling

Three exceptional conditions may occur: Errors in calling on and controlling the modem; Communications errors; and Asynchronous interruption ([Break] key and[System.Reset]). Errors of the first type always occur as a result of an I/O call to the modem handler through CIO. The error condition is signaled to the application via a CIO error return. The second error type includes buffer overrun, framing errors, parity errors, and loss of carrier. These errors occur during the application with a CIO error. Instead, these errors set internal error flags which the application may check with the STATUS command. (See Section 2, The Six Standard Input/Output Command Interfaces.) The third type of error, [System Reset], results in an open IOCB to the modem. (See Section 2, Handler/Operating System Interface.)

Certain errors may occur on any I/O call to the handler:

ERROR
FROM

80 hex (128 dec) [BREAK] key I/O abort handler

85 hex (133 dec) IOCB not open
CIO

86 hex (134 dec) bad IOCB specified CIO

8A hex (138 dec) timeout (no modem response) handler

Error 85 does not occur on OPEN or STATUS since CIO performs an implicit temporary OPEN for these operations. Other errors are specific to certain I/O calls:

CALL ERROR
FROM

OPEN 81 (129) IOCB already open
CIO

84 (132) Invalid command (no I/O direction) handler

96 (159) Port (modem) already open handler

INPUT 83 (131) Write only handler

88 (136) EOF (means carrier loss) handler

OUTPUT 87 (135) Read only handler

88 (136) EOF (means carrier loss) handler

XIO 92 (146) Function not supported handler

OUTPUT 84 (132) Invalid command (not recognized) handler

establish 98 (152) Illegal user-supplied buffer handler

[System.Reset] results in the closing of the modem IOCB. When the modem IOCB is closed, any data not yet sent from the output buffer will not be sent. [System.Reset] affects the file closing by "mashing" the system to its reset state. This operation is described in Section 2, Handler/Operating System Interface.

Buffer Use

The 256 byte input and 64 byte output buffer areas allow effective concurrent operation between the modem performing full duplex communications and the 6502 CPU running an application. The application may not, however, use the serial I/O channel while the modem is active. As the modem receives a communications byte, it interrupts the 6502. The modem handler fields the interrupt and saves the incoming character in the input buffer. Data held in the buffer is subsequently read by the application via an input call through CIO to the modem

handler. Similarly, output data first goes into the output buffer. As the modem completes sending each output byte, it interrupts the 6502 for more data. The handler takes the interrupt and gives the next buffered byte to the modem for transmission.

The modem handler is responsible for keeping track of the data in the buffers as the data arrives and is sent. Status is maintained by the handler, keeping track of how much data each buffer holds at any time. The application program has access to this information by PEEKing at it. Each buffer is circular (a ring), holding up to one fewer bytes than the buffer's size. Each buffer is accounted for by internal, user-transparent pointers. There are two byte-count bytes which may be PEEKed at by the application if it needs to know the quantity of data backlog. These counters are located as follows:

Location $400 INCNT Number of bytes currently in input buffer.

Location $401 OUTCNT Count of bytes currently in output buffer.

The buffer area is always formatted the same, even if the modem is being used for INPUT only or OUTPUT only.

The applications program may PEEK at INCNT and OUTCNT to determine the number of bytes currently in the input or output buffers. All other parts of the buffer area are for handler use only. There is no defined way for the application to use any of this data.

The output buffer is always 64 bytes in length. As soon as data is put into the output buffer, it is drained by the handler at the maximum rate of the modem until the buffer is

emptied. Should the buffer fill, the handler loops for space, waiting for the modem, and returns to the application through CIO only when the byte is placed in the buffer. If the application does not wish to be held, it will have to check the buffer use before making the output request.

The input buffer is 256 bytes in length. It is drained by the application as fast as the application can handle the data, until the buffer empties. When the handler is drained, it loops and waits for data from the modem. If the application does not wish to be held, it will check the buffer use before making the input request. Should the buffer overflow, an error flag will be set which may be interrogated by the STATUS command. (See Section 2, The Six Standard Input/Output Command Interfaces.) Input buffer overflow indicates that data is lost. The handler retains the data in the buffer and discards the new data from the modem.

Handler/Operating System Interface

The handler interfaces to the Operating System in the following ways: Initialization (cold start); System reset (warm start); Break key flag; Interrupt handling (IRQ); System vertical blank timer, and CIO (including the "put byte" call by which the application bypasses CIO). There are also a number of fixed bytes/words in the Operating System RAM area reserved for use by the modem module handler.

Calling interfaces between the application and the CIO, and between the CIO and any handler, is described in the ATARI Home Computer System Technical Reference Notes. In addition to operating under CIO access, the handler supports the PUT

BYTE entry made by 8K BASIC directly (bypassing CI). BASIC enters PUT BYTE with the A, X, and Y registers as set by CIO. However, the zero page IOCB is not established (except ICAX1Z and ICAX2Z), and any checking normally done by CIO is bypassed and performed by the handler.

The handler monitors the System Break key flag (BRKKEY) whenever executing any loop which either continues indefinately(as when waiting for the modem where there is a possibility the modem may not respond), or whenever the loop may exceed one second. If the [Break] key is detected, the handler returns to the caller with Error 80(hex). (See Section 2, Error Handling.)

The handler/modem interface is designed so that pressing the [Break] key does not produce any undesirable side effects. (Preferably, the modem should abort an operation when the [Break] key is pressed at the same time as the handler aborts.)

The handler includes code for fielding the IRQs which are generated by the modem. The handler's interrupt code address is installed in the Operating System RAM vectors (Serial Input Ready, Serial Output Read, Serial Output Complete) when the modem is OPENed or, subsequent to OPEN, when the modem operation is RESUMEd. The handler contains a special serial bus driver for the modem. When the modem is CLOSEd or SUSPENDed the handler reinstalls the Operating System RAM interrupt vector for Serial Input Ready.

The power-on default conditions are as follows: All errors are cleared; translation and parity controls are set to zero; and the Analog Loopback Test is off.

The effect of a warm-start ([System.Reset]) is to close any file open to the modem and to reinitialize the handler and modem to the power-on.

742. To Mike Ishler about my disk drive problems:

My mail message to you got bounced back to me again so I presume you didn't receive it. If you've run out if ideas, that's OK, so have I. I guess I'll buy a new one or get it fixed. Anyway here was my message:

Thanks for your latest recommendations. Here are the results of my latest disk drive inspection:

The drive was made by Northland Corp.

The belt looks like it's intact and in place.

The spindle doesn't turn after the head resets.

The busy light comes on for about 5-6 seconds after I put a disk in and close the latch. Then it goes out. However the disk spindle doesn't turn.

I turned connector J10 around. Besides the fact it no longer lined up with the other connectors, the head resetting sounded kind of sick so I put it back the way it was.

There doesn't appear to be any wires under the metal shield around the LSI chips.

How likely would it be that the motor is dead? Or a ROM?

I'm still trying. Thanks for the help.

Rick

By the way. Which of the following addresses is correct or will both get my message to you?

743. ACTION! Language

Newsgroup: comp.sys.atari.8bit
Date: 1987-11-23 14:07:18 UTC
From: rastroobossc@violet.waterloo.edu
Message-ID: <4204@watdragon.waterloo.edu>
Source record: 117347

I am currently developing a run-time memory manager for the Action
programming language. This run-time manager will serve two functions.
First, it will allow for dynamic memory allocation and disposal. The function
New () takes as input the size of a requested block and returns an address
to this block. The procedure Dispose takes as input the address of a block
and returns it to the internal heap.
Second, the memory manager will allow the user to call procs and funcs
recursively. This is accomplished by pushing parameters and local variables
onto the internal stack via the procedures PushStack () and ShoveStack ().
Similiarly, the user can pop items off the stack with the function PopStack ()
and procedure HeaveStack ().

If you are interested in using some of these programming aids, feel
free to contact me via the net or via electronic mail.

Lastly, I have one question for you knowledgeable Action! programmers.

While developing this run-time manager, I have frequently used TYPEs and
POINTERs to records of TYPEs. I have found a error in the way Action!
compiles code with respect to record TYPEs. At least I think that it does,
on my cartridge at least.
Let me provide an example, and then I will explain how Action! compiles
this.

```
MODULE

TYPE BlockNode=[CARD data
CARD next]
BlockNode POINTER FrontNode

DEFINE True="1"
DEFINE Nil="$FFFF"

PROC Test ()

BlockNode POINTER CurrNode

CurrNode=FrontNode
WHILE CurrNode <> NIL DO
IF CurrNode.data = PrevNode.data THEN
RETURN (True)
ELSE
CurrNode=CurrNode.next
FI
OD

RETURN
```

The problem lies in the execution of the statements after the ELSE clause. I have reviewed the object code that the Action! compiler produces and have discovered these things. Action! accesses fields of records by using indirect indexed addressing, ie. (addr),Y. As it compiles the IF clause it produces code that uses indirect indexed addressing to retrieve the values for CurrNode.data and PrevNode.data. This code includes LDY #1 and DEY, since the data field in the record is located in two bytes, that are offset by 0 and 1 respectively from the start of the record. That's easy you say, and I agree, but the problem occurs when Action! compiles the line, CurrNode=CurrNode.next. In an attempt to optimize the code, the object code produced does not explicitly LDY #3 and DEY to access the next field. Rather, it expects the code produced by the IF clause to have set the Y register to 1, and simply INYs the Y-register. However, the IF clause does not leave the Y register as 1, but as 0, and then when trying to access the next field in CurrNode.next, we access 1 byte away from it, which really screws up tree traversals and linked list traversals.

So far, I have been fixing this by including explicit LDY #1 [$A0 $01] instructiions in my code. But I am wondering, has anyone else had this problem, or can they verify it on their cartidges?

Thanks for your time, if my essay has been too confusing, reply and ask more questions. If the above example I gave does work, (it shouldn't) I will post the original problem from my micro (when I get a modem for Christmas) including the source code and object code in assembly language form.

My subscriptions to Antic and Analog have been relatively error-free for over four years. When an issue is missing (twice for Analog) a phone call has gotten a replacement issue without question within a couple of weeks. The Antic disk ordering has produced a disk in hand within two weeks. There are times, however, when I think the quality of the articles and programs take a real nosedive (especially in Antic). Like when they both publish the same utilities or they republish a game that was primitive years ago and the "new improved version" is slow and primitive today. Or when they think a Basic version of an assembler game they published years ago is appropriate now (i.e., LIFE). It makes you think they have run out of material and are stretching to find something useful for the 8 bitters.

> Atari decided their drives should run at 288 RPM! (Does anyone know WHY?!)

At 288 RPM you have a little better than 8 mS more per revolution (compared to 300 RPM) which gives you time to squeeze that "one last (128 byte) sector" (and gap) onto a track. The bit density on the media is slightly higher than normal. At 300 RPM, you would have gotten one fewer sector per track (without shrinking the gaps, and thereby reducing margin).

The Action! toolkit contains an include file called
ALLOCATE.ACT and it allows dynamic memory usage. I don't know if it
is as nice as yours though, I never tried using it.

Apparently, as Tom Johnson has reminded me, the ACTION! toolkit already has a procedure for allocating memory dynamically. Does anyone have time to post a short summary of some of the better routines that are available in the ACTION! toolkit? Does it support real numbers, recursive proc and func calls, what else will it do? Perhaps, you could also give your opinion about the quality of the product.

Source record: 117353
Cross-posted to: comp.sys.atari.8bit,comp.sys.amiga

Hello and SEASINGS GREETONS -

I am new to both the comp.sys.atari.8bit group as well as the comp.sys.amiga group. From what I understand one/both of these machines has the potential for what I need to do. I am hoping that someone out there in net.land will be able to help me figure out what is needed for the following:

-hook up a VCR to a pc
-organize, access and modify video content (ie. on a "frame-by-frame" basis)
-superimpose graphics (free-hand and text) on video content
-integrate sound (e.g., narration/music) with video/graphics content

So what you would end up with is sort of like one of those movies you see in highschool science class where there is a mixture of people in labcoats talking, "live footage" of some phenomenon and then some graphics superimposed on the "live footage" which the narration/music describes, etc.

I saw a commercial on TV awhile back of a guy who is raving about how he can make his own "music videos" etc with his machine and how you can't do that with a Mac (or something). I don't remember the name of that particular machine but any help anyone can offer will be GREATLY APPRECIATED.

Thanking you in advance...
Sincerely,
:-)

755. Re: Double density format questions...

Newsgroup: comp.sys.atari.8bit
Date: 1987-12-19 02:24:07 UTC
From: hans@umd5.umd.edu
Message-ID: <2149@umd5.umd.edu>
Source record: 117259

There are actually three fairly common disk formats in the Atari world:

Single density (FM), 128 byte sectors, 18 sectors per track, 720 sectors per side, single sided. This is commonly called "single density".

Double density (MFM), 128 byte sectors, 26 sector per track, 1040 sectors per side, single sided. This is commonly called "enhanced density".

Double density (MFM), 256 byte sectors, 18 sectors per track, 720 sectors per side, single sided. This is commonly called "double density".

The 810 drive is single density only.

The 1050 drive supports single and enhanced density.

The never released 815 drive would have been double density only.

Various other vendors made drives which support all three densities: Indus, Rana, Trak come to mind, there probably are others, too.
There also are upgrades for the 1050 which make it work in all three densities.

There are also the double sided versions of these formats supported by some drives (i.e. Percom, maybe others, and now the XF551).

Disk i/o is done by sending sector numbers to the drive, which converts them to track/record(/side) as appropriate. Sector numbers start at 1. For single sided drives the conversion is the obvious one, but I do not know how the mapping is done on double sided drives. -- But: send me an XF551 (or a Percom drive) and I will find out for you!! :-)

Since the bootstrap in the os rom does not know about double density drives, there is a special hack in the drive firmware for this: Sectors 1 - 3 are treated as if they were 128 bytes long, even in double density. They actually are 256 bytes long on the disk, but only 128 bytes are transferred from/to the sio interface.

There are three methods for changing a drive's density that I am aware of:
1. Most drives will automatically determine the correct density when a disk is inserted.
2. Some drives have front panel controls to set the density.
3. Some drives (all multi-density drives except the 1050, as far as I know) will accept a configuration command over the sio bus.

A drive's density may be determined in two ways:
1. The Status function returns bits which allow one to distinguish between the three popular densities. All drives support this.
2. Some drives (see comment in 3. above) support a command to read the

configuration record.

Dos (2.0, 2.5, xl, and Mydos, at least, I haven't looked at any others) set flags to indicate the sector length, where the byte count/forward link are located, etc., whenever they are performing i/o operations. These just happen to be in the boot block (see "mapping the Atari"), and when a boot block is written they reflect the state of that disk drive. This is the information the boot code uses when loading the rest of Dos. Dos 2.0 then uses the status function to determine the sector size for all configured and attached drives.

Dos 2.0 apparently has 99% of the code needed to support double density drives. The main things missing are a mechanism to change density of a drive, or even to let Dos know that the density of a drive has changed, and the code to write a good copy of DOS.SYS to a boot disk. There were patches for this posted a while back, and if needed I may be able to find them. I don't know if this support was continued in Dos 2.5.

On double density disks the vtoc is still at sector 360, and the directory follows. These sectors are now 256 bytes long, and DOS allocates 256 byte buffers for them, but only 128 bytes are used. Since the sector link in Dos 2.0 and 2.5 is only 10 bits wide, only 1023 sectors per disk can be used. Sector 1024 in enhanced density is used for an extension of the vtoc and sectors 1025 to 1040 are not used. Mydos supports drives with lots more sectors, including double sided. I don't know how they get around this, perhaps by doing away with the file number in each block, and thus expanding the size of the sector link.

Well, this is probably lots more than you ever wanted to know about this subject, so I'll quit now. I will be glad to answer any additional questions.

756. Analog?

Newsgroup: comp.sys.atari.8bit

==========

Just wondering if anybody knows what the deal is with Analog?
They skipped the november issue, and I have yet to see a
December issue! I remember that they skipped last July or
August, and then the following 2 or 3 issues (the last I
received) were very late in coming out. Does anybody know
if they're ever gonna come out with another issue already?!?!?!?

-Ray

PS - Merry Christmas one and all! :-)

Whoah!

The XF551 has hit the USA also, within the last couple of weeks. I know
that Federated stores have them, and some others locally here.

Also, ADOS was recently finished as far as beta testing was concerned. Not
ages ago, weeks ago.

I'm looking for folks to help me get our 8-bit software archives straightened out. Specifically, I need people to volunteer to test software, and write up little blurbs about what each frob is, how well it works, etc etc; ie all the little tidbits you wish you had when you were pawing thru a catalog that you snagged off a bitnet server, for instance.

Anyone who's interested (or if you think you might be interested, or you've heard of someone who's interested... I'm not picky) please let me know, and I'll send you the the current version of the catalog file, and the list of things that need to be reviewed. I'm not enclosing it here, cause it's getting pretty big.

Please folks, help out a poor overwhelmed hacker!

Remember that companies that advertise in magazines have to have their
proofs into the publisher approximately 3 months before publication date.
Three months ago (or more), most dealers thought they would have XF551's
before Christmas.

Moral: Just because you see it in an ad, don't assume that that means
they actually have them.

I'm looking for some kind of utility that will create an AUTORUN.SYS file to boot a BASIC program of my choice (only one program, no menus....I want to be able to specify the filename to boot when the autorun file is created). I have tried to use a sector editor to modify the filename in an existing autorun file. The problem with that was (it seems) the program placed a fixed number of bytes into BASIC's line buffer....and my filename was shorter then the original (I haven't tried to disassemble the 2 sector autorun file and see what the problem really was).

Anyway......does anyone out there have a handy little utility they wrote that they would like to share?? If not, I guess I have a software project to work on. Post or mail....I'm not picky!

For the benefit of those of you who do not have an account on DELPHI, I saw
a message there from Matt Ratcliff about the XF551: His local dealer (in
St. Louis Mo. area) just got his first shipment. Many people have "heard"
that Atari wasn't going to ship '551s until late January, but Atari has
proven them wrong. What a nice Christmas present for us 8-bit Atari "fans!"

I do have a set of drawings but they are pretty shabby and really won't
photostat to be really useful. The best way to fix that problem is to
do the following:

1) Replace the regulators.

2) Solder them in. Do not use the sockets. The sockets have caused
90% of all failures on the RFD-40.

3) Check the rectifiers and replace if necessary.

If you do all of the above It should work for another 5 years or
more without trouble.

As a note:
The RFD-40 has a jumper on the board that will allow the
Atari to see it as drives 5-8 instead of 1-4. Kinda neat if you
want more online storage.

If all of the above fails then email me your name and address
and i can either exchange your old controller or repair your
old one.

771. Info atari instructions. Please read and retain for future reference.

Newsgroup: comp.sys.atari.8bit
Date: 1987-12-25 15:40:24 UTC
From: ravi@mcnc.org
Message-ID: <2717@alvin.mcnc.org>
Source record: 117275
Cross-posted to: comp.sys.atari.8bit,comp.sys.atari.st

This message contains the latest info-atari instructions to subscribers. Please go through it (even seasoned users!) and retain for future reference. Of special interest to BITNET users (and interent users with access to bitnet) is a section on accessing the 16-bit program libraries at the Univ of Houston.

The info-atari moderators.

Welcome To Info-Atari.

1. Sending Messages

You may send messages to all "subscribers" by address-ing it to

info-atari8@score.stanford.edu

and/or

info-atari16@score.stanford.edu

Administrative messages should be sent to

info-atari{8,16}-request.

Please do NOT send general messages to this address. Your moderators get enough mail as it is!

2. Ground Rules

All messages should be in good taste. Commercial mes-sages and advertisements are not permitted. When answering a question, please consider carefully whether the answer should go to the whole list, or just to the person who asked the question.

The following ground rules should make the use of this (or of any other) mailing list much easier:

* never send a message that a totally irrelevant to the mailing list's purpose to a mailing list. This espe-cially includes any expressions of irritation at another list member.

* never forward a message that is totally irrelevant to the mailing list's purpose to a mailing list.

* when replying to a message on a mailing list, reply only to the sender of the message unless the reply is of interest to the entire mailing list.

* avoid inserting the message being replied to in a reply, especially in a message going to a mailing list. The context of the reply should be clear from *your* reply and from various mailer functionalities such as Message-ID.

* when replying to an earlier reply that violates the previous rule, ABSOLUTELY DO NOT make matters worse by adding your own violation.

December 25, 1987

3. Archives

Archives are kept in several places in formats available to everyone. As described below, if you are on ARPANET/DDN you will probably find it more convenient to retrieve files from the archive on radc-softvax.arpa using FTP. If you are not on ARPANET/DDN, or are unable to use FTP, you will be able to retrieve files from archives distributed over several Bitnet hosts by sending mail (notes) to a program called LISTSERV.

3.1. Archives on radc-softvax.arpa

Files from radc-softvax.arpa are available by FTP. FTP will work only for hosts directly connected to ARPANET/DDN. Please obtain local documentation and advice for the FTP user programming running on your host. There are two directories under the anonymous account. One for atari8 and one for atari16.

FTP to radc-softvax using login:guest and password:guest. To get the current list of available atari16 files do a 'get atari16/files.doc'. All of the atari16 files are stored in the atari16 subdirectory. If you need any other information, contact Marc Poulin.

The archive is maintained by Rodney Peck (Peck@radc-multics.arpa) and Marc Poulin (Poulin@radc-multics.arpa or Archives@radc-softvax.arpa).

3.2. LISTSERV

LISTSERV provides access to files for everyone who can send mail, independent of their location. Note, however, that intermediate notes have been known to refuse to handle long messages or have damaged them in transit. LISTSERV provides a number of features which you can access by send-

ing mail (note) to LISTSERV. Only the barest minimum are described herein. On Bitnet messages should be sent to your nearest LISTSERV (the one from which you receive the info-atari digests). (If your address is not on Bitnet, an address for file servers is given below.) All mail sent to LISTSERV contains command lines. LISTSERV will respond by return mail. No subject is necessary in such mail. For more information send the command

INFO

3.2.1. List Names

The list_name for 16-bit Ataris is INFO-A16. The list_name for 8-bit Ataris is INFO-A8. These list names are used by Bitnet addressees for subscribing and unsubscribing

and by everyone for obtaining back copies of news digests. The list_names for programs stored in the archives are PROG-A16 and PROG-A8.

3.2.2. (Un)Subscribing

If you are on Bitnet you may add or remove yourself from the distribution list. It would greatly convenience the moderators if you would do so when you no longer wish to receive digests.

The command to join the list is

SUBSCRIBE list_name User_name

The command to remove yourself from the list is

UNSUBSCRIBE list_name

It would be most convenient if users took care of their own subscribing and unsubscribing, but messages to INFO-ATARI-REQUEST{8,16}@SCORE.STANFORD.EDU will still be accepted.

3.2.3. Accessing Program & Digest Archives

All digests are in the archives. There is a separate program library. You can obtain copies of files from LIST-SERV by sending a message in the specified format.

If you are on ARPAnet (or gatewayed to it), your mail concerning 16-bit Atari information should be addressed to

LISTSERV%CANADA01.BITNET@CUNYVM.CUNY.EDU

Mail concerning 8-bit Atari information should be addressed to

LISTSERV%TCSVM.BITNET@CUNYVM.CUNY.EDU

To obtain a list of files in the file server, the command is

INDEX list_name

The command to obtain a specific file is

GET list_name file_name

for example,

GET INFO-A16 87-00076

December 25, 1987

If you want to learn more, send the message

HELP

The moderator of the 8-bit program library is John R. Dunning. This library is not yet available for use, and further information will be posted to both newsgroups as it becomes available.

3.2.4. LISTSERV Moderators

The person to contact if you are having problems (un)subscribing is Harry Williams (harry@marist.bitnet). The moderator of the 16-bit digest archives is Peter Jasper-Fayer (sofpjf@uoguelph.bitnet). The moderator of the 16-bit program archives is Richard Werezak (carson@mcmaster.bitnet). The moderator of the 8-bit archives is John Voigt (sysbjav@tcsvm.bitnet). The moderator of the 8-bit program archives is Arnold de Leon (adeleon@hmcvax.bitnet).

3.2.5. Information Concerning 16-bit Archive Organization

The digests are numbered sequentially as they come in. Sometimes the files arrive here out of order, or with missing ones, or with extra ones or with mail from BITNET users requesting information. Often the moderator has to logon to LISTSERV and re-name the files according to the "Subject:" line within it. Those "Subject:" lines are what end up in the indexes (in both "-A16" lists)

The program files are largely extracts from the digests (INFO-A16). As far as possible, they are numbered the same as the digests they came from. Other programs were inserted somewhere in the list. The numbers of these "inserted"

files were selected so that they would appear in the index at about the correct CHRONOLOGICAL sequence. If no programs were included in the digests, and no contributions were received, then those spaces in the index numbers were left blank.

3.2.6. Supplemental information for BITNET users

Bitnet sites normally cannot make a connection to an internet site (such as Score) and FTP files over, so you do not have direct access to the archives on radc-softvax.arpa from your BITNET site. However, BITNET has some sites with all the good stuff, so you can get files from there. The LISTSERV's at CANADA01 and FINHUTC have old digests, and the ATARINET server at Univ of Houston has most of the best programs. You can get to the LISTSERVs by saying

TELL LISTSERV AT FINHUTC GET ATARI FILELIST

or

TELL LISTSERV AT CANADA01 GET ATARI FILELIST

to get a list of files. To get a specific file if you know it's name, you can say

TELL LISTSERV AT <HOSTNAME> GET <FILENAME> <FILETYPE>

To get stuff from the Univ of Houston server, you can say

TELL UH-INFO AT UHUPVM1 ATARINET HELP

or

TELL UH-INFO AT UHUPVM1 ATARINET INDEX

for further instructions. After you know a file's name, you can get it by saying

TELL UH-INFO AT UHUPVM1 ATARINET SEND <FILENAME> <FILETYPE>

I am looking for opinions on whether Printshop (and Companion plus libraries) is a better package than Xlent's Typesetter (and Rubber Stamp plus Page Designer). I received some Xmas money and could buy either for my old 800. Flexibility, compatibility with other utilities (MicroPainter and DOS, for example), and unique features are all of interest.

Kermit65 has become my terminal emulator of choice ever since it was posted here on the net. I love the way you can switch between 40/80/Atari modes.

Is Kermit65 capable of generating the tilde character? I was using Chameleon in the past; to generate the tilde (why couldn't Atari just put it on their keyboard) you typed a "control <delete/backspace>".

Also, I noticed a bug (I think). When hitting the break key followed by a <CR>, the program goes into "nuts mode" printing G's all over the screen. The only way to regain control is to reboot. Has anyone else experienced this?

Last but not least....Is the source for this program available anywhere?

778. Autorun a BASIC program (a request)

Newsgroup: comp.sys.atari.8bit
Date: 1987-12-28 22:52:20 UTC
From: jhs@MITRE-BEDFORD.ARPA
Message-ID: <8712282252.AA00986@mitre-bedford.ARPA>
Source record: 117282

Paul Kopp's desire to autorun a BASIC program might be easiest to satisfy by using Turbo BASIC or FrOst BASIC. A compiled program can be autorun by the method described in the Turbo BASIC documentation. I think you name the runtime system AUTORUN.SYS and name the compiled BASIC program AUTORUN.CTB or something.

Other than that, there have from time to time been articles in the various Atari magazines telling how to do this with standard Atari BASIC, including type-in programs etc. I'll see if I can find a reference.

You might want to try and scare up a copy of Smart Dos. It used to be
packaged with the Rana Drives. There were a coupla versions, 6.1D, 8.1D. A few
others also.

Anyway, with the DOS they supplied a program to set up a special
autorun file that will run a basic program. Really works slick. I'm not sure
if it will (the auto made program) work with DOS 2.0 or 2.5, but it would
seem reasonable that it would. Just have to rename the filename.AR1 to
reflect the Atari Autorun syntax.

If someone can let me know if this program is able to be passed
along, I would be more than happy to post it.

Speaking of the XF551, can anyone at Atari tell me why they didn't ship SpartaDOS with the XF551? It's _easily_ the best thing out for an 8 bit, (I resist temptation here to list the massive numbers of Sparta features I have seen) And already supports hard drives (a growing commonality, at least around here.) Did anyone contact ICD? Or wouldn't ICD go for it, or what?

Maybe it's just that old wishful thinking. But it's not all just wishful! I have a new 256K+ based typsetting program on my detroit board! And am beta-testing a multitasking Atari OS (yes. Stop. Back up 8 words. "multitasking.") Extended memory support is HERE!

If you want to autorun a BASIC program then the easiest thing to do is
to get a copy of "Compute!'s Third Book of Atari". In it there is a program
called Automate which allows you to type in BASIC commands and then it will
write the ml code for it. It is very short. Unfortunately, since it is
from Compute! there is a copyright problem. I really wish Compute! wasn't
so tough on copyrighting programs such as these. I mean, is it really
worth it? The program is quite short, not even a hunderd lines. The
easiest thing to do with this program is to give it one BASIC command...
RUN"D1:YOURFILE.BAS" and then you're on your way. It is on page 167 of
the above mentioned book. A very useful utility!

Glenn.

787. Yet Another 1050 Problem

Newsgroup: comp.sys.atari.8bit
Date: 1988-01-01 00:50:54 UTC
From: shafferj@bknlvms.BITNET
Message-ID: <8801010048.AA04632@ucbvax.Berkeley.EDU>
Source record: 117291

I've seen lots of 1050 drive questions here before, so I'm hoping someone
can help me.
About a month ago, the belt in my drive came off. I thought nothing of it
and put it back on. Over the course of the next week or two, it began to come
off with increasing frequency. I took it to the nearest service center,
thinking that it was only a problem of the belt stretching from normal use.
They told me that they would have to diagnose it themselves. About a week
later, I got my drive back. They told me that they needed to install a "motor
shim kit" and adjust the speed. (There
was no speed problem noticeable in
normal use.) The drive worked fine for about a week, then the belt came off
again. I put it back on and subjected the drive to heavier-than-normal use for
about another week with no problems whatsoever. Just today, though, it came off
again. Obviously, it has become quite annoying to replace it. I'm reluctant to
take it back for service, however, because I don't want to pay for something
that they didn't get right the first time.
Can anyone help me? Is this problem common, and can it be fixed? And what
did the service center do to my drive, and why?

I would appreciate replies directed to myself, so that I don't have to
wait for the digest.

Thank you in advance,
James Shaffer, Jr.

That's tough. If you want to log in to your favorite mini/mainframe, you are going to have to buy a modem, and possibly software to run that modem. If you want to use one of those Hayes-compatibles, you will also need an RS232 interface (P:R: connection or the Atari 850) and cable. From there use the school's dial-in numbers. Otherwise, there is nothing you can do unless you are a hardware superguru. The cheapest setup is to buy a second-hand 1030 modem (it runs at 300 baud, it isn't produced anymore) with its built-in terminal software (extremely primitive, and it doesn't emulate anything useful). You'll have to hunt around for those. A more sophisticated setup is

1) Get the Atari SX212 300/1200 modem w/ terminal software. Check with Atari dealers or mail-order companies. May need a disk drive to run the software.

2) Get a Hayes or Hayes compatible modem from almost any computer dealer (prices will vary) that can go 1200 or 2400 baud. You will need an RS232 interface and cable (available from mail-order houses or Atari dealers) and software (850 Express (Shareware), Amodem 7.x (???), or Kermit-65 (PD, posted here before, but I missed it 8-(). Kermit-65 is the only one of the 3 with decent terminal emulation, but the others have good features also. You will also need a drive here and this setup can cost bet. $300-$400. But at least if you switch computers, you can still use the modem.

Couple of notes: If your system has not been expanded to at least 48K ram your only option may be the 1030. In that case, it may be better to just start again with a new computer system. Also, all these options assume that you are able to connect the modem to a standard phone jack in some way. They cannot communicate through the phone receiver (like the old acoustic modems).

791. Re: Autorun a BASIC program (a request)

There is a public domain utility called MENUPLUS that, amongst other things, has an option to create autorun.sys files to run a BASIC program. The BASIC program can only be a few lines, but it is used typically to execute a RUN of the actual program you want. I have used it to create an autorun.sys to automatically boot up AMODEM - the little basic program I wrote that is attached to the autorun.sys prints in large letters "LOADING AMODEM", and then runs AMODEM. The version of MENUPLUS that I have is V5.5. It has one annoying feature that it tends to change one of the characters in the BASIC program (randomly?), so it may require minor experimentation.

You should be able to get MENUPLUS (and lots of other goodies) from your friendly local user group (hopefully you have one!)

792. Display list problems

Newsgroup: comp.sys.atari.8bit
Date: 1988-01-05 20:42:00 UTC
From: Makey@LOGICON.ARPA
Message-ID: <8801051242.12196.Makey@LOGICON.ARPA>
Source record: 117296

I have been experimenting with display lists on my 800XL and have encountered a couple of strange problems. The first is that if I try to use the very bottom scan line on the display, the picture rolls. Adjusting the vertical hold on the monitor doesn't help. There doesn't seem to be a sync signal, or something, as I can slow down the roll to *almost* a stop, but it doesn't latch into position when it should. There is no problem with using the top scan line of the display.

The second problem occurs when I try to use a wide playfield. In this case, the 3 leftmost columns on the display show the border color instead of the background color or any text that is there. On the right side, the last column is non-existent (black) and the second-to-last column has a moving snow-like appearance. Once again, I have tried adjusting the monitor but it doesn't help. I am not just running off the edge of my CRT.

Some notes: I bought my 800XL, serial number 189429, in June 1986. It has the GTIA chip, "B" OS ROMs, and all of this happens with an Action! cartridge plugged in. I use a B/W composite monitor, not a TV.

Has anyone seen anything like this before? Is it an inherent problem, a configuration problem, or just my breath?

:: Jeff Makey

Source record: 117298

In vol88, issue 2 of the Info-Atari8 Digest, hackit@ai.mit.edu
(john Bunch) writes,
> I would like to know if anyone out there knows of the status of
> speedscript,ei. is it in the public domain. I would like a copy of it
> to use with cc8 If anyone knows of the status of it pleaslease let me
> know.

I wrote to the Editor of COMPUTE! a while back about using Speedscript
for the Apple 2 in an educational setting (a microcomputer cluster).
I was informed that it is definitely NOT in the public domain, that
COMPUTE! retained the rights to it, and that we would have to purchase
a copy of it for each machine.

They are, of course, perfectly within their rights at COMPUTE! to hold
to that position. No argument there. But the exchange does point out
a subtle (in the minds of users) but critical (in the minds of publishers)
issue. For a piece of software to be in the public's hands is not at all
the same as being in the public domain.

Software gets into the public's hands by being published (then by being
pirated, black bagged, stolen, ripped off, etc., but we won't go into
the little matter of those "unofficial" distribution channels right now).
Software goes into the public domain when the copyright holder says,
"OK, if anybody wants it, go ahead and copy it."

I'm sure John understands this distinction, or he wouldn't have brought
up the issue; he would simply have asked for the program. But I thought I
might point out for anyone who wasn't aware that most of the magazines that
publish software specifically reserve all rights to the software. If we want
the program, we're supposed to buy the magazine or the disk, just like the
more traditional commercial ware.

I can't see Richard Mansfield coming out with the sheriff to throw somebody
in the slammer for typing in a copy of some program out of a friend's back
issue of COMPUTE! rather than buying the back issue. But I've noticed
references to a number of bulletin boards in this Digest, and people who
are sysops or club software librarians need to keep an eye out at least for
the better-known pieces of magazine software (?periodicalware?), and not
put them on the boards without the copyright holder's permission. As for
who holds the copyright, in almost all cases it is the MAGAZINE, not the
author who holds it, and therefore holds the power to grant permission
to copy the program.

Sorry about the soapbox speech, but after needing asbestos gloves to
read the letter form COMPUTE!, I thought I'd share with everyone,
especially people associated with bulletin boards or software libraries,

the publisher's totally unambiguous position.

By the way, COMPUTE! wanted me to buy a copy of the MANUAL for EACH machine as well, a totally unreasonable position when they sell the program disk separately from the manual. The result: we bought Apple Writer for the cluster. Much more expensive, but no high handedness. On second thought, maybe I *can* see him coming out with the sheriff....

I have received both the January and February issue of ANTIC although
I simply haven't had the time to post an index of the articles as I
have been doing for the past couple of years. I hope to resume later
this month with the February issue although I do not plan to go back
and post the January index.

One of the highlights of the January issue was the disk bonus program
called SuperCopy which is billed as one of the fastest and easiest
multi-file disk copying programs ever published for the 8bit Atari.
I have the disk but haven't tried this program yet. The featured
applications program is TopShelf, an outstanding all-around database
program that offers many powerful features and is easy to use.

The January issue was also the annual shoppers guide with over 100
of the best products for the 8bit Ataris. If you are a fan of SSI's
wargame simulations, you know that most games require you to use the
keyboard numbers to move various directions. There is an article and
patch to allow you to use your joystick to direct your forces.

Hope this dispells any rumors of ANTIC's demise. I may have been
the source of some of the doubts since I haven't posted the Index
for the last two months. Sorry...

I should point out here that this is not strictly true for all of
the Atari- specific magazines: ANALOG states (both in their
mag and on the DELPHI Atari SIG that they support) that programs
published in their magazines are NOT public domain, but after
the issue date of the magazine, the programs may be "made available"
to user groups, BBSs, etc. (Since their publication has been
behind, once the mag's have come out, the issue date has passed. So,
recently, I have been able to legitimately give a friend of mine
a copy of a program obtained from ANALOG/DELPHI-Atari-SIG as soon as I
get it myself. ANALOG does not give permission to distribute the
text of the articles describing the programs, however.

Is there any way the Atari game cartridges for the video game systems (like 2600) can be modified to run on the 8 bit machines?

Also is there any way of converting the cassette based games I have to disk format?

I have Super 3D Plotter II (from Elfin Magic Co. a/k/a Randolph Constan[sp?]), which is a great program for 3D graphics on the 8-bits, but has never been updated to even use the "extra" 16K in the XLs, much less the banks in the 130XE. If S3DP2 used the banks, it could probably allow some good features that larger CAD programs have, but had to be left out of this one. (Mr. Constan mentions this as a future possibility at the end of the user manual, but says that he hasn't decided whether to expand S3DP2 for the XL/XE machines, or upgrade the program for the ST machines. In the latter arena, there are already some powerful contenders.) I for one plan to write Mr. Constan and ask for this. Anyone care to join me?

I also have the Synfile XE (or whatever the 130XE version is called), and it supposedly uses the "upper" 64K in the 130XE. My wife uses it with our 130XE, but I don't use it much and can't tell what it may be using the memory for (the "in-core" index and maybe other "buffers" I would guess). Now if I can just convince my wife to try using double-density data disks...

Lastly, I have OMNIVIEW XL/XE which will use the 64K as a RAMdisk without special DOS support. I haven't taken the time to try it yet, but when I get back into programming instead of just "using," I'll give it a shot.

Of possible interest to the Net:

A friend of mine here in the Boston area, Barry Kassindorf, has acquired an interesting collection of Atari 8-bit hardware and documentation, some of which he is willing to sell.

Specifically, Barry has a couple of Atari 850 interface boxes and several Trak Double Density drives to sell. Also, he has several extra copies of the 800 hardware manual and of De Re Atari.

Barry's phone number is (617) 877-4977.

Reasonably speaking, I believe not. As I understand it, the 2600 uses a completely different processor (not 6502) than the computers. I'm not certain of this, but if so, you would have to convert the machine code. You may as well rewrite the program.

>
>Also is there any way of converting the cassette based games I have to disk
>format?

Possible. I have seen utilities that convert cassette boot programs into disk boot programs, but I'm not sure where you would get one. As you know, cassettes are not used a whole lot anymore. Good luck.

Again, I may be wrong, but modifying the OS of the Atari can interfere
with the operation of the MIO. Such changes may involve the internal parallel
bus handlers. This fear may be unfounded since I don't know the technical
details of the Omniview or the MIO. Anyone know?

Does anyone have a list of 8-bit Atari virus programs, if any exist? I searched in vain for one on CompuServe, and I don't have the money to do an extensive search of private BBSs.
I decided to try to obtain a list for two reasons: the recent CHRISTMAS EXEC virus on Bitnet, and the appearance of _two_ IBM PC viruses in recent months.

804. 800XL Hardware Problems

Newsgroup: comp.sys.atari.8bit
Date: 1988-01-11 20:17:00 UTC
From: henry_k@apollo.uucp
Message-ID: <399db0e9.c998@apollo.uucp>
Source record: 117158

My Atari 800XL appears to have a hardware problem. When I RUN the program:

```
10 PRINT "HELLO"
20 GOTO 10
```

It works for a second or so, then changes the color map, prints garbage at the bottom of the screen, and hangs. A RESET is required to bring the machine back to life. Occasionally, I get error 12 (non-existent line number) instead.

Although many things work OK (including the self-tests :-)) I would like to fix this problem. ATARI Customer Service at 1-800-538-8543 appears to be non-existent. This leads me to the following questions:

1) Is there a known fix for the above problem?
2) Are there any known design problems which require hardware changes to fix?
3) What is the state of ATARI these days; including their Customer Service department?

Please reply directly. If deemed appropriate, I will later summarize to the NET.

/keith

The address space of the 2600 and the 8 bit computers are very different,
and the video display is organized *very* differently. It is not practical
to attempt to run the game cartridges. Even given the source for the games,
it is a fair hassle to do a conversion.

I believe that Atari's customer service line has been down for quite a while. As for the problem, is that the only case in which you have a problem? Do you have trouble with non-BASIC programs? I have not heard of this specific problem, but if BASIC is the problem, your BASIC ROM may have been fried.

<.....decoding attempts deleted.>

I had this problem once before with a file, and was able to solve it with a little help. Below is a portion of an article which appeared a while back on comp.sys.atari.st:

I experienced problems when uudecoding disasmbl.tos, too. But as I noticed,

that the program has been posted by someone on BITNET, I examined the file

more closely. And this is, what I've found:

1. Some lines are short of a few bytes.

-> Fill those lines with trailing blanks until they line up with

all the other lines.

2. There are a lot of tildes ('^' == 0x7e) in the file.

Tilde is not a valid character in an uuencoded file. But I happened to

remember a posting by someone on the net who found out, that these tildes

started out as pointers ('^' == 0x5e).

-> Change all tildes (0x7e) to pointers (0x5e).

Next: Now uudecode that modified file.

In addition to this, sometimes a file contains 'grave markers' in place of spaces (on an 8-bit Atari, they appear as the solid diamond character). To fix this problem, simply replace each grave marker with a single space. I've found that SpeedScript's global find-and-replace feature works well in repairing files plagued with these problems. Hope this helps...

816. ANALOG - ST/Log bought out

Newsgroup: comp.sys.atari.8bit
Date: 1988-01-16 14:48:33 UTC
From: bruce@ektools.UUCP
Message-ID: <1010@ektools.UUCP>
Source record: 117170
Cross-posted to: comp.sys.atari.st,comp.sys.atari.8bit

This notice regarding ANALOG and ST/Log was posted on Delphi:

ANALOG is in the process of being bought out by a very large publishing company based in Los Angeles, California. The publishing company will provide printing, distribution and subscription services for ANALOG and ST/Log Magazines. For the most part, the editorial content will still be lead by Lee Pappas, Clayton Walnum and the assortment of contributing editors currently adding their prose to the magazine.

The first issue of ANALOG and ST/Log that will be published under the new company will be the March, '88 issues. These issues will be on the news-stands in late January, '88. After the re-introduction, ANALOG and ST/Log magazines will be published monthly with approximately the same coverage and substance as was previously made available.

Subscribers will continue to receive their issues as normal under this new arrangement. ANALOG will be installing an answering machine on their Worcester, Massachusetts phone number sometime this week. The machine will give more precise details regarding the publication dates and subscriber information.

817. Booting disk software on an 800XL reliably.

Newsgroup: comp.sys.atari.8bit

I have been having trouble getting disks booted on an 800XL. Sometimes it takes 4 or 5 tries to boot up (say) Boulder Dash Construction Kit, following directions in the package or not. Usually it doesn't even hit the disk... just gives me notepad. Once it starts talking to the disk everything usually goes like clockwork.

I've tried turning on the computer first, the disk first, holding down various keys during the boot, etc... what is the accepted sequence?

I have an 800 with two Percom DD drives, and an 800XL with 2 1050s (as well as a Zenith terminal and an Amiga 1000 with 4.5 Megs... I also pull down mumble mumble bucks a year as a Sr Software Engineer... that is to say I'm not a novice).

You boot the computer with the disk on, when you are dealing with
a 130xe. And I would think that would be true of most systems, I
have to do the same with 3B5s and 3B2s at work. If the disk isnt
on, the proccesor won't find it when it boots, and will be unaware
it exists.

From: cfchiesa@bsu-cs.UUCP
Message-ID: <1895@bsu-cs.UUCP>
Source record: 117176

Here's the scoop on booting disks on the 800XL:

1) Turn on at least Drive 1 BEFORE turning on the computer. Wait for the little red light to go out (about 5-8 sec).

2) Place an autoboot disk (not ALL disks CAN autoboot, for one thing) in Drive 1.

3) Whether or not you have any cartridges in the slot is up to you; if you're gonna use, say, ACTION!, you need to have that one IN. SPACE INVADERS or whatever, you'd want OUT...

4) If not using a cartridge, to boot WITHOUT "built-in" BASIC, hold down the OPTION key, and continue holding it down while you go to step 5. If you want to boot WITH built-in BASIC, DON'T hold anything, just go to step 5!

5) TURN ON THE POWER TO THE COMPUTER!

At this point, the disk should begin twirling, the light on the drive should come on, and you should hear the bee-bee-bee-bee-beeps of the disk-read operation.

If you don't mind my asking, how'd you get to own an 800XL with all those drives, and NOT KNOW THIS stuff? Seems well-nigh inconceivable to me; I'd think it'd not only be in the manuals, but would be just about the first thing ANY computer owner would pick up in the first two hours of ownership...

Oh well, maybe I'm biased; I'm quick with these things. If it can be flow-charted, I can comprehend it.

Subject: 8-Bit Music

Could anyone give me some information about MIDI options for the
8-bit Ataris, if there are any, specifically the old 800?

Thanks,
Rory Wohl

826. A few questions....

Newsgroup: comp.sys.atari.8bit
Date: 1988-01-20 03:14:43 UTC
From: SAGAPO@SBCCVM.BITNET
Message-ID: <8801200318.AA23410@ucbvax.Berkeley.EDU>
Source record: 117180

Okay... a few questions.....

1) About the Upgrades for the 130XE, namely the 1 and 2 MEG, where can you find the directions for the mods? How do they effect the 130XE in relation to program use? What do you have to sacrifice? I realize that there isn't a company that produces the mods and I will have to do most of the wiring myself, but I do a few things with electronics and I think I can hack it.

2) The Multi-tasking program of Terry Conklin. If you have more than 128k..i.e. the above mentioned 1 meg... is it possible to set up the program to use more than 16k for a task?

3) In answer to John R. Dunning's request for help to get the 8-bit software archives straightened out: I am here. I need the progs to download from an IBM 3083 to a 130XE, but other than that, I am free. How does UUNECODE work? If it is not too much trouble, would someone explain how it works and possibly send me a copy? It would me much appreciated...

Thanx in advance,
Ron Trenka
SAGAPO at SBCCVM

The above statements are from my own mad delusions and do not represent anyone's opinion, including my own... 'Hold that thought...'

827. kermit65 and XM301

>
> Glenn Euloth

The two versions of kermit65 are identical except that the one "with"
is "with" an RS-232 handler attached (prepended or appended, I am not
sure which). CDY's OmniCom is "shipped" ONLY WITHOUT a handler (unless
someone has tacked one on). If you had an 850 or very compatible rs-232
controller, you could use kermit65 "with" the standard handler. I'm not
familiar with the XM301, but I believe it requires a special, i.e. different,
handler. I seem to recall seeing one posted that was written in ACTION! and
included autodialing and emulation of other Hayes features in the handler
itself. In any case, you DEFINITELY will need to load a handler along with
the bare bones kermit65 just as you do with OmniCom, in order to make it
work with ANY serial comms device.

It is usually convenient to select a handler, then tack it on either in front
of or at the end of the terminal emulator program. The DOS loader (program
that runs when you use the L command) then will load both the handler and the
terminal emulator "automatically" (what else, its a computer after all!!??).
Concatenating the two load modules is easy: just copy the one you want first
to a file with the desired name, e.g.

C<RETURN>
FILE1.OBJ, TERMPROG.COM<RETURN>.

Then copy the one you want second to the SAME FILE, but use the /A (append)
switch on the end of the destination file's name, with no spaces, e.g.

C<RETURN>
FILE2.OBJ, TERMPROG.COM/A<RETURN>.

Deciding which to put first and which to put second may be harder; in general
it is probably safest to put the handler file first, as the terminal emulator
program probably will most likely be designed to start running upon being
loaded. This has to do with which type of "load vector" the files end with.
Sometimes binary files are incompatibly assembled so that neither order will

work. In that case, you have to go in and patch the final load vectors of one or both using a sector editor/debugger. However, if you find an XM301 handler and put it in front of kermit65 or OmniCom, I suspect you will be "on the air".

Source record: 117182

I saw an ad in a recent Antic from a place that sells used equipment. They had the 800XL for about $64 as I recall. I don't have the address handy but can dig it up if you can't find it.

New ones are still available and are under $80 in any case. Your friend might be smart to just buy a new one. Computer Mail Order or Electronic One are probably good sources. CMO: (800) 233-8950, E/O: (614) 864-9994.

By the way, when you say "destroyed", do you mean he ran over it with the family pickup truck, or is it physically intact but just no longer working, for some non-obvious reason. If it's the latter, I might be interested in acquiring it for fixing up or spare parts. I'd be willing to pay a small amount for it, which would perhaps offset the cost of the replacement one. Get back to me if your friend is interested and I'll give you a phone number.

Full directions for every upgrade mod ever produced are specially maintained on the Club II BBS in Detroit. There are tons of mem-upgrade files online. If anyone ever produces any upgraded-memory related PD software/text, we'd appreciate it if you'd help the sys stay complete, too. (313) 334-8877, 300/1200 baud. File area 29.

> 2) The Multi-tasking program of Terry Conklin.
> Ron Trenka

Whoa! I'm not the author, just Beta-testing it. And no, it's really limited to 16K. Otherwise, you'd have an absurd jumble where software was loaded onto 2 concurrent pages in RAM, software would be coded to be _multiply_ assembled at the same (rotated 16K page) address, and youd have to jump across pages. Arrgh, what a mess.

Terry Conklin

833. CDY, OMNIVIEW, and OmniCom

[I attempted to e-mail this message to John Sangster, but my path for him no longer works; anyway, this ought to be of general interest here.]

Do you have a correct (and working) e-mail address for CDY? I have one from around 8 months(?) ago, and I tried sending him e-mail, but got no reply from Mr. Young (nor an "undelivered mail" or any other response from any mailer along the way). He used to respond to e-mail (he even replied to a news article of mine by e-mail once).

Alternatively, do you have any information about any features added to OmniCom (since the ~4/87 version) or OMNIVIEW (since the full-ASCII support was put in - no, I don't have that version of the chip yet...)?

Thanks,

Nick DiMasi (...!ihnp4!ihlpm!njd)

P.S. Thanks for the shareware OmniCom... it will come in handy when I upgrade my OMNIVIEW chip!

Checks of the local Toys-R-Us store has shown sales of the XE Game System to be cruising right along. A friend says when he checked, they were completely sold out.

If you could, I would appreciate it if you could call your local retailer and find out how they are doing in your area. If sales of the new machine are good generally (and not just here) I am seriously considering taking time out to develop a new game (which had been 20% developed some time ago, but stopped due to a shrinking Atari market at the time.)

Please post replies to the net. Any sales news/numbers from Atari would be appreciated as well.

P.S. It seems important to note that the people I have talked to are not only getting the game system, but a disk drive as well.

Source record: 117190

There is NO version of Hack for the Atari 8-bit, simply
because Hack is an extremely space-intensive (i.e.
memory-intensive) game. Just consider - the hack
dungeon consists of over 20 levels, each of which may
need to be stored, rooms, hallways, monsters, and all. 48k
of memory is simply not enough.

There is a version of Rogue available for the Atari 8-bit,
however (since Rogue only saves one dungeon level at a time,
such a thing is possible). It is produced under the Epyx
label, I think.

You mean 'self-test mode', don't you? An 800XL doesn't have a notepad mode.

Anyhow - how warm is the room your computer is in? I've found on my 800XL
(with one 1050 drive), that if the room is too cold, I have to try several times
before I can get the disk booted.

>I've tried turning on the computer first, the disk first, holding down various
>keys during the boot, etc... what is the accepted sequence?

Turn the disk drive on first, then the computer. If you don't want BASIC, hold
the option key down while you turn on the computer. If the boot doesn't work,
try again until it does.

>I have an 800 with two Percom DD drives, and an 800XL with 2 1050s (as well as

I have been following the situation here in the Western Suburbs of Chicago and have found the status about the sames. Our Toys R Us, Kay Bee Toys and Child's World all sold out their supply of XE game machines. Some of them had a pretty good supply, too.

The only down note is that software is very scarce. All the games they had before Christmas were older games such as Tennis, Ms Pac Man, etc and these were going for $19.95 to $24.95. Since Christmas, I have seen two new games, One-On-One and Archon. What I find positive about this is that they are marketed by Atari, even though they were developed by a third party company. This is an absolute MUST. Third party companies are not going to support a system that isn't even supported by the company that developed it. One example is Radio Shack's Color Computer III. This is a relative new system with even less hardware on the market than Atari computers but I just got the new RS sale flyer. Guess what? In the software section for the CoCo 3 is Shanghai and Microscopic Mission, two games I would like to see for the Atari 8bit (Shanghai is supposed to be released for the ST, it looks like a fun game). They also have Where In The World Is Carmen Sandiego, which I have been waiting to come out for the 8bit Atari. The point is, these games are marketed by RS and sold through their stores. Activision and Broderbund have little invested other than some time. Atari needs to take this approach a little more than they have in the past. Even if it is just for games that are going to be released on cartridge, they need to do it.

One other comment on the XE game machine. Few disk drives were sold here because none of the stores I have visited have ever received any. The manager of the Kay Bee Toys told me that many people had ask him where they could get them and he ask me as a member of the local Atari users group. The sad truth is, I couldn't send him to any place within 20 miles of here. Our users group is inviting new owners of the XE game machine to our club meetings to see how they can get the most out of their machines but until they can buy a disk drive, there isn't much we

can do for them. We made up flyers and the manager of the Kay Bee Toy store has been giving them to buyers of the XE-SGS and to anyone who asks about more information on disk drives, etc. We hope to get several new members and help out confused owners in the process. Other groups might try something similar in your area. Try offering three months free membership or free software for joining, etc. The response might be better than you expect.

^^^^^^^^^^
I assume that you are referring to the Atari XF551 DSDD drive? (If not, what drive(s) are being sold?!?) How do these people like this drive?

I haven't talked to my local Toys-R-Us, Kay-Bee Toys, etc. , but from the recent ATARI SIG traffic on Delphi from people who have, I see that the XEGSs are a "hit" in at least several major cities in the U.S.

If you decide to develop a game for the XEGS, keep in mind that it should be compatible with the rest of the 8-bits too (or at least the XL/XE machines!). There are a lot of us "old 8-bitters" out here (as just a LOCAL [Chicago area] BBS listing I did late last summer showed), and a new game every once in a while helps us keep the "old faithful 8-bit" out of the closet (in my case, my 8-bits are my ONLY home computers - so far... Tramiel(s), where's that 680x0 UNIX(tm) box?).

(what is a line eater, anyhow?)

[the following review is an in-depth look at the Atari XE Game System. I had the opportunity to really give it the once over, and did so because of the limited review given in Antic. This is expressly created for distribution of any form, as long as the copyright remains intact, whether by BBS or Compuserve or your local newsletter. Magazines contact the author through the system below.]

"Hands-on the Atari XE Game System. An In-Depth look
Copyright 1988 by Terry Conklin
from Club Network - (517) 372-3131 / (313) 334-8877

Atari's first new 8-bit computer in some time has hit the streets, and preliminary magazine reviews have been pretty scanty, so when a shiny new machine came in, I gave it the works.

First impressions: The XE Game System is built well. At least as well as the 130XE and perhaps a bit better. The base unit is solid and the separate, detachable keyboard is nicely weighted. The POWER switch, perhaps one of the most used switches on any game machine, wasn't the greatest and could have been better made. On the other hand, the big pastel colored START/SELECT/OPTION/RESET buttons were fine.

The detached keyboard is a new entity to Atari 8-bits, and I really liked it. It isn't super-light, and is well sized and shaped for setting in one's lap for programming. I say programming because many long time Atari owners are giving the XE Game System a serious look as a second machine, largely because of the keyboard. However, the console keys are on the main unit, not the detached keyboard, so some of it's usefulness as a "lean back and relax" work device is inhibited

The HELP key is on the keyboard. And I noticed that it has the same distinctive feel of the rest of the keyboard, even though it's a large round button like the console keys. This means that the XE Game System keyboard is not made of the same unit as the 130/65XE keyboard, and thus if something breaks, you can't tap that large collection of parts. Otherwise, the keyboard is completely identical to the XE keyboard in feel, shape and layout. You almost wonder why they bothered to make a new one.

The cable that attaches the keyboard to the main unit is about 12 inches long and plugs in on the left hand side in a recessed port. It uses a connector much like the 850 interface printer port, much like a joystick connector but with more pins. I noticed that someone thoughtfully included a little nub on the connector so that when you plug in the

keyboard cable, it fits snug and is not likely to come out when you pull on the keyboard (which is inevitable.) The keyboard also has hooks at the back that allow you to connect it to the main unit, forming a single piece. This was easy to do and I found myself switching from lap to desk-connected as the software I was using dictated. The main unit and keyboard connected together make up a 14 X 15 inch square, so be sure to have plenty of desk space for this system.

The main unit has the cartridge slot on the top, like an XL, but slanted at an angle matching the XE-style design, (though there is no cover protecting the cartridge slot as on the XL.) The joystick ports are on the right hand side, underneath and at an angle. This is the same sort of approach used first on the 1200XL and later on the 1040/520ST-FM. While it doesn't make it really easy to switch joysticks/lightguns/etc., I didn't have any trouble with it at all, and it does make it more aesthetically pleasing and easier on the joystick connectors to have the cable coming out of the computer in the general direction of the rest of the joystick.

On the back of the unit I ran into something of a suprise: an audio jack! A second later I realized that the XE game system has changed the connector for the monitor output. Unlike the 5-pin DIN plug monitor jack on other 8-bits, the XE system monitor output is supplied on two phono-plug jacks; one for sound, one for composite video. The television plug is next to these, but confusion is unlikely.

Continuing across the back, there is no parallel bus connector. There isn't on the 65XE either, (which this really is,) but it means you cant use parallel bus peripherals like the MIO (Multi-IO) from ICD. Next is a standard SIO port to connect to Atari peripherals. Amusingly, in Atari's current school of design, they stamp an icon above each connector on the back to indicate what should plug in where. On the ST for example, there is a telephone over the RS232 port, and a diskette over the disk drive port. Following this school of thought, there are 4 icons crammed in over the SIO port! At least things are consistent. The power connector is identical to the previous XL/XE connector.

Having wrapped up the physical description, how does it run software? Like a 65XE. In fact, absolutely like a 65XE, which is no suprise since that's essentially what it is. But for safety's sake, I decided to give it a full range compatibility test.

In total I tested 8 cartridges and a lot of disk software. One of the cartridges was a 600/800XL system diagnostics cartridge as well. Even this cart claimed that the system was an XE, and everything ran fine. During the testing of all this various software, I did notice some sort of twitch in the video. It only happened once every five or ten minutes that I saw, and the diagnostic cart didn't make it happen, but I checked the monitor and it was fine. I'll be investigating more XE Game Systems to find out if this is a factory trait or just a individual case.

A couple options come with the XE Game System that weren't previously available. Most notably the light gun and a couple new cartridges. The XE Game System also has the game Missile Command built-in. Wherever it is, it's awfully well hidden. I turned the machine on with no cartridge and it came up in BASIC. When I held down the OPTION key, it came up with the XL/XE Self Test screen. Needless to say, it IS a 65XE. I never got a chance to test Missile Command because quite frankly, I didn't even remember it was there!

The Atari light gun is at once the most fun addition and the biggest disappointment. One of the two cartridges that comes with the system is a bug-shootout game. At first, it seems rather simple-minded, but the more I played the more I enjoyed it, and it gets quite challenging. Unfortunately, the challenge isn't one to hone your skills on. The light gun is easily the cheapest component of the system. The aim was _noticeably_ off, even at point blank, and the "gun sights" formed into it's plastic case were completely useless. Sometimes you get the distinct impression that the gun's aim actually changes. I might attribute that to reviewer error, but having over half-million point scores on the gun game "Hogan's Alley" in the arcades, I have spent at least a hundred hours with a good, workable system and this doesn't come close. Still, after a while I was able to get 80+% "hit ratios" on the included game, so it can work. Owners of the game system may find that they "learn" the aim of their own guns and enjoy them more.

We also tested the game cartridge and gun on a standard 130XE and 800XL, and they work fine. Perhaps Atari can be convinced to release the gun separately as an option for existing Atari owners.

The other cartridge included with the system is Flight Simulator II. This in itself is an impressive feat. Flight Simulator II is a _128K_ cartridge, making it the largest Atari cartridge ever produced. Flight Simulator II itself is an amazingly accurate 3-D solid-graphics flight simulation that lets you fly a Piper PA-28-181 Archer II, a single engine 148 Mph aircraft. It also has a "Europe 1917" mode that lets you test your flying skill in World War I combat against enemy planes and ground targets. One advantage of the cartridge FS-II is instant load times. The original disk Flight Simulator II would occasionally pause to load additional scenery information from diskette. The FS-II cartridge instantly changes scenery for constantly smooth flight. I did not check to see if the FS-II cart. could read Flight Simulator scenery disks.

Of all the system, there was only one incompatibility that I discovered, that being a difference in the operation of the RESET key. On the XL/XE computer line, when you pressed and held down the RESET key, the system would be held, reset, in never-never land. This was often handy if you hadn't quite gotten the next disk in the drive yet or needed a second before the machine tried to boot. It also made a special technique for saving extended-memory RAMdisks possible, where if you locked the machine up, you could hit and hold RESET, insert a cartridge, release and hit RESET again, then remove the cartridge. The machine will _always_

cold-boot, but without ever having to shut the machine off, thus the RAMdisk contents are intact.

On the new XE Game System, the RESET key didn't reset on the way down, but reset when you release the button (on the way back up.) Holding the button in this halfway up state proved to be difficult at best. Since the XE Game System is otherwise identical to the 800XL, it is not unimaginable that some game system owners might want to add memory (a.k.a. a 256K standard upgrade,) in the future. The difference is more or less negligible.

All in all, the XE Game System is a fine Atari 8bit. As a new machine for people interested in gaming, the massive selection of Atari games makes it a far better value than Sega's & Nitendo's offerings, and the graphics are, of course, terrific. Add to that the fact that it is a real computer, with all the versatility thereof, and it can't be beat. As a machine for new Atari owners, I judge it a better value than the 65XE, given the better keyboard and included software and gun. As a replacement machine or upgrade for existing Atari owners, it's a close call. The detachable keyboard is a joy to use. On the other hand, the lack of any parallel bus capability is a big minus. More and more people are putting hard disk drives on their 8-bits, and the "big" Atari 8bit (>256K of memory, several drives and/or a hard disk) is getting common. It might make a good "partner" machine.

Any way you look at it, the XE Game System is a good machine that will make it into a lot of homes bringing new owners, new users, and yet more customers for Atari 8-bit software. For 8-bit owners everywhere, "Thanks Atari."

The Child World here in the western Chicago suburbs had nearly a wall of
XE game machines. After Christmas, they were nearly sold out.

Problem is, mail order seems the only way to find a good selection of software.
Local stores are not carrying much, if anything.
(But they are covered with C64 stuff - YUCH!)

Epyx made a version of Rogue for the ST (they don't even carry that anymore in their latest catalog). They never intended to make an 8bit version.

ANTIC magazine published a version called Arogue that is pretty good considering the memory limitation. I have a 48K machine and it works fine. It is in BASIC, so it is easy to cheat if you are so inclined. It uses redefined character sets which makes it a little hard to read on a color tv using the RF modulator. Might be a lot better if you had one with a composite video input. Would be much better if used with a color monitor. It was reviewed by one of the regular readers here on the net last summer/fall when it was printed in ANTIC. He beat me to it, I'm pretty slow at typing in magazine listings because my time is limited for such frivolous pursuits. I barely have time to look up the spelling of all these words in the dictionary :-) .

Source record: 117201

I tried to call CDY Consulting (maker of the OMNIVIEW 80-column chip and software to use it) today (1/29/88). The number I have for them, from the latest (4/1/87) documentation I have from them, is (214) 235-2146. Calling that number gave me a "not in service or disconnected" message. I called Directory Assistance for area code 214, and asked for CDY Consulting in Richardson. The D/A operator had no listing.

Does anyone out there know where CDY moved to? (I am assuming that he just moved, and didn't "disappear.") I tried sending him mail at an e-mail address I have for him from ~last May, but got no reply or "error messages."

p.s. to John Sangster: if you saw my earlier article, and tried to send me mail, I didn't receive it. Please post your e-mail address, or call me at (312) 790-3435 and leave it (please spell out "words") on my answ. machine if no-one answers. By far the best route has to be the ICD MIO/SCSI disk combination. Plus it has the advantage of having a SCSI disk you can put on a future ST for just the cost of the controller (ICD has one of those too!)

You can't go wrong with ICD.

I work for a computer store here in Portland that specializes in Atari products and we've been doing a fairly brisk business in XEGM's. Not as much as in ST's, but a noticeable improvement over the other XEs in sales. We've been sellng disk drives to about 25% (my estimate) of XEGM buyers. These haven't been the new Atari drives, since we can't seem to get them (where ARE they, Atari?). For a while we were selling old 1050's, but since they ran out it's been all Indus GT's.

Careful, the 1200XL ROM is substantially different from the other XL and XE systems. Be sure to check if the MIO will work with a 1200XL.
Otherwise you might have to grab this excuse to upgrade to an 800XL or a 130XE.

Sounds like from your description (dropping into the notepad) that you may have a bad connection between your 800XL and your drive; if you're hearing the infamous (thhhhhpt) sound (!), that means your drive isn't connected. (to hear what that sounds like if you're not familiar with it, just unplug the drive and turn on the computer)

I would suggest swapping cables (if you have extras), checking for bad/loose pins, and maybe cleaning the contacts..

>>a Zenith terminal and an Amiga 1000 with 4.5 Megs...

This isn't the same problem, but this might explain some wierd disk activity that could be the cause of problems such as the ones above.

Although the Atari computer components themselves are well-shielded as a rule (the 1050 disk is not really), the cables are not really shielded. I have found when I connected more than one drive or printer off the interface serial port, I get spiratic disk errors (which sometimes ruin the data on the disk), and some retries on sector reads when booting DOS (not something that's a ususal occurance).

What I have attributed the problems to, since I had no problem with the computer before I moved to an apartment, is the MASSIVE amount of RFI (radio interference) in the area (my television gets a massive amount of interference from various sources, including what appears to be an unknown transmitter nearby). I believe that some of the more powerful interference is being picked-up inside the disk drive circuitry, causing the drive to act up.

I have looked into the various hardware-related problems including a very comprehensive look at my drive and different disks, etc. It is definitely not either.

I am curious if similar problems have occurred like this in Atari or other manufacturers' equipment. Also, has anyone shortened the interface cables on their Atari equipment to see if this helps? Perhaps it is being picked-up through the AC line? Please post answers to these or related queries unless they would not benefit others.

Becuase I tend to be lax in sending each individual who replies to my postings a note of thanks, I thank anyone who replies in advance.

Unfortunately, the MIO only works on 130XEs/800XLs and I *think* the 600XL.
The Supra board is in the same boat. I can only suggest to Brian that he
may need to upgrade/downgrade (depending on how you look at it) his machine
before pursuing this further.

I have a atari 800XL and run a small BBS system up in the Scranton,Pa
area. I have the 800Xl with the Newell 256K Ramdisk.
Although I think it is a great machine CMO seems to differ.
Computer Mail Order no longer carries the 800Xl series.
I tried to get one for my friend. I had to call over 20
stores to find one. Atari no longer makes them so maybe they
finally run out of them

864. Modem communications on an 800

Newsgroup: comp.sys.atari.8bit
Date: 1988-02-05 03:01:18 UTC
From: ciaraldi@cs.rochester.edu
Message-ID: <6548@sol.ARPA>
Source record: 117218

I'm trying to help someone out, so bear with me if I
mess up on some details. I've only talked to him on the phone,
I haven't even seen his system.

This guy has an Atari 800 with a hard disk (don't know the brand).
He wants to use it to talk via modem to a VAX and emulate
a VT100 terminal. So, he has the following questions:

1) How do you connect a modem to an 800? Isn't there a
built-in serial port of some kind? Can you use this for a
modem, or is it needed for disk or printer communication?
If not, can you add a serial port easily? We would need
at least 1200 baud.

2) Can you get an 80-column by 24-line display on 800?
Do you need an add-on board? Where do you get one?
(no Atari dealers in town anymore, I think).

3) Assuming you can do the above stuff, is there software to emulate
a VT-100 terminal? It would be nice if it could also
dump the screen to disk and/or printer on operator request.
If not Vt-100, how about some other terminal (other than
a "glass TTY" with no cursor control at all!).

I hope someone can tell me if any of what we want to do is possible.
Or not, if that is true.

Thanks,

Mike Ciaraldi

Ok,first off I've seen a term program(PD) that will emuninate the VT100
and 4 others systems as well. I will post the address A/S/A/P.
(Saw add in Antic)

To connect the Modem on an 800 you might need a Serial converter
to connect the two. You can make a homemake ringer from a relay
and connect it to a joystick port. (I have plans if you need them)

Good luck,

==========

TEXT OF CONFERENCE ON DELPHI REGARDING ANALOG BUYOUT
JANUARY 17, 1988

Andy> I'd, first, like to welcome all of you attending this conference. My
name is Andy Eddy and I'll be moderating the CO.

Lee> First, ANALOG has signed contracts with a publishing company in
LA. That company is LFP, Inc....Larry Flynt Publishing. We expect to have
the next issues of both mags out in 3 weeks. Let me give a few words about
the changes...First...Larry Flynt has little to do with daily operations of
the company...as a whole. He will have nothing to do with the editorial
contents of either magazine. Changes you will see include new (glossy)
paper, a heavier stock inside as well as a heavier cover. More color pages
throughout, INCREASED distribution, Much improved service, and a steady
frequency. What you won't see is ads for Hustler and the like.
LFP, Inc. also publishes a Mens fashion mag, a running mag, a new
automobile mag, a motorcycle pub and a Heavy Metal mag. With many more non-
pornography titles on the way.

Andy> Thanks, Lee. So the fears..that this will be anything like..Hustler
will not materialize. This will remain the same Analog as before..but
with some changes in the "production" end..not the editorial.

Lee> OK. There WILL be changes.. Because I won't have to deal with such
things (as much, anyway) as distribution...subscription problems, and
production, I can spend more time on editorial...that goes for Clayton as well.

Andy> So you don't see anything but beneficial changes for the mags?

Lee> Actually, let me say this...the only way someone will know we are
owned by another company is a small blurb on the staff page. As far as
changes go, I expect an even more steady stream of quality editorial
since it will be the main direction of our time working on the mags.

Maurice M.> Okay. I want to get this subject out of the way now especially
in light of recent messages in the forum. Certain people have hinted that
there will be changes in the magazine because of whom the ownership is. The

point, I think has been refuted. However, DF Scott has in recent messages hinted that several of us writers were in a "dilemma" over the ownership change and might no longer write for ANALOG. I would like to put to rest any fears readers might have about mass-defection of writers by asking you, Lee, if you are aware of any other regulars "leaving" because of this ownership change.

Lee> No, not at this time. Let me respond to your comments. While I don't whole heartedly agree with Larry Flynts views. I am looking at what that company can do for our magazines. They don't know ANYTHING about what we publish, they (LFP, Inc) are leaving us alone in what we do. To them profit is what they want, editorial content is 100% up to what we do. They'll make the magazine look better, distribute it better, and put out a quality looking product, it's still up to me, Clayton, Maurice, Charles Johnson, Andy Eddy, MAtRat and the rest to put out a good magazine in product. To answer Maurice's question, other than Scott, no one has more than batted an eyelash over the buyout in terms of who it is. After the initial shock wears off on the buyer's name, they settled in and want to get back to work.

Maurice M.> Good to hear. I simply wanted to address the subject because I wanted people to be aware that Scott didn't speak for all of us. I'll step down now.

Lee> Last Monday is when Michael Des Chenes and I signed. We are waiting to get them back from LA now then it will be official.

Clay> Anyone who is interested in the terms of publication and how to submit articles may send me a self-addressed, stamped envelope and I'll see that you get our writer's guidelines. You can send requests to the PO Box 23 address in the magazines for now.

Andy> Also with Analog's liberal policy of letting programs go onto BBS's after 1 month from issue date (that is right?), everyone gets to see the stuff they publish.

Clay> Yes, Andy.

Mike Brown> Will we be able to get back issues of both magazines and disks as in the past? Or will these "Classic" issues become collectors items?

Lee> Yes! LFP, Inc is purchasing our entire supply of back issues. Including disks, 8-bit Extra's and so on. We expect to offer disks at a lower price and the availability should be MUCH better.

JIMGAR> Thanks. My burning question is WHY???? Wasn't Analog a profitable venture?

Lee> WHY is a complex question. First - WHY NOT? ANALOG was myself and a partner, Michael Des Chenes. As you may have noticed, Michael never spent much time on Delphi and while I have gone to over 100 Atari shows and ComDex's, etc., he has not. Michael has been bored doing the same thing for 7 years and wants to try something new. In addition, I couldn't see the company growing much further the way things have been, so this gives us a

chance to expand greatly....plus I'll be working on new publications, both computer and non-computer related in the next few years.
Also, LFP, Inc. offered us a very good deal...and who really knows how long Atari will keep going. This way I can expand on my interests and do other things along with the Atari field -- after all, I have been doing the for 7 years. A long time!

JIMGAR> In other words, the whole thing got out of hand?

Clay> A company can only grow within the facilities it has at hand.

Lee> Right...We needed to expand, and as do airlines, insurance companies and so on. We were bought out to expand our capabilities.

WHITEWIZARD> you said that the analog depends on the 8-bit...Does this mean that you might stop publishing in the future if the 8-bit fails (ANALOG, not ST-Log)?

Lee> ANALOG depends on the 8-bit market ...Lets say that advertising right now isn't overwhelming and ANALOG would most likely take a new heading (orientation) in the event 8-bits REALLY dwindle. I could see a change happening probably this year some time...

WHITEWIZARD> Would you combine ANALOG and ST-Log again?

Lee> Again, it is mostly up to the ANALOG staff, not LFP, Inc. Yes, I could see us doing one mag--but here is the problem. The ANALOG name is the best known, if we put in ST-Log then the mag becomes a general Atari mag again. If we kill ANALOG and continue ST-Log...well ANALOG has the more known name and that would be a mistake. Chances are ST-Log might have some 8-bit coverage...but that is all up in the air right now. When we are in place after a couple months we'll look at the whole picture.

MADMODIFIER> With many software publishers spreading out to the Amiga..... Is there any chance that Analog might do the same?

Lee> I have plans to do another computer oriented mag but can't say much (exactly nothing) about it.

MADMODIFIER> You mean we might see AMIGA LOG <grin>?

Lee> No Comment. But I hope to have a new project out in late Spring.

Mike Brown> I would like to suggest that you run some type of a readership poll in your first new issue to determine what your readership looks like now.

Lee> Huh...in what way? Between ST and 8-bit?

Mike Brown> Well I imagine that the complexion of the readership has changed somewhat. It might be worthwhile from a marketing standpoint.

Lee> You mean between 8-bit and ST??? Sophistication?

Mike Brown> Well that and just what people are interested in reading about. What their needs are "today".

Lee> We have the "bingo" cards in the mag every month and poll those to see what people are using...however we have talked about doing another mail-in campaign...a more in-depth look. Remember that Delphi users are more into their machines than many other average users.

Mike Brown> Maybe, but I guess my point was that at least in the 3 user groups I belong to things are in a state of "change".

STeve M.> What direction will ST Log be taking in terms of content? General readership, programming, or what?

Clay> I can't see much that will change in ST-Log. Is there something you WANT to see changed?

STeve M.> No, just was hoping there were not going to be any drastic changes now. Thanks.

Lee> I feel we have a good balance of information, sophistication and programs. I think Clayton, myself and our new west coast person will have more time to look at each issue well in advance and look at it's contents to see what blend of information it has...thus boosting the magazines quality...(not that it needs boosting <grin>) in addition, hopefully we'll add more pages too.

Clay> The combination we've had in the past has worked out well, I think. I don't see any reason to change it. (More pages would be nice.)

Lee> No, I certainly haven't seen any complaints about the balance of material. Keep in mind that I'm moving from New England (fresh air, no traffic, nice scenery) to LA (smog, Lots of Traffic and more smog) for the CAUSE. In other words...If I didn't see a tremendous potential in this I wouldn't do it!

There was a device known as the Atari 850 interface which provided 4 serial ports (2 full ports, one teletype, and forgot what the other was) and a printer interface (centronics parallel). It has not been made in years, unfortunately. However, ICD (I think; it's been a while) makes a device called the "PR: connection", or something like that. (P: being the printer device, R: being the default serial) It runs between $60-100 bucks, and can usually be found advertised in Antic or ANALOG. It will allow you to put any RS-232C modem on an Atari. Atari also sells a direct plug-in modem (XM130), but I'm fairly sure they never released the 1200 baud model.

>

Again, Atari was _supposed_ to release an 80-column adaptor for the 800; it was even previewed at a show or two (like a lot of things.. :-). I don't think it was ever released. However, CDY Consulting (in Texas) sells a number of upgrades for the 800 and XL lines, including a product called OmniView, which allows 80-column output. It is also supported by quite a few programs. They usually advertise in Antic as well.

There was a package called Chameleon, which would emulate a VT-100, and emulate 80 columns by scrolling the screen to the right. I _think_ a newer version supported the OmniView. Antic has their own software catalog they publish every once in a while -- included in there was Chameleon and a number of other programs, all at low prices.

In a previous article, Mike Ciaraldi asks about VT100 emulation and serial communications on the Atari 800.

You can connect the Atari 800 to any modem using an Atari 850 Interface (it has 4 serial ports, 1 print port) or an ICD PR-Connection (it has 2 serial ports, 1 print port). Another alternative is the new Atari SX212(?) 1200 baud modem... it connects directly to the computer.

A program called KERMIT65, which is available for free from various sources, supports 80 column VT100 emulation. The 80 column screen is generated in high resolution (320x200) so the characters are in a 4x8 matrix. It isn't the best looking text... but it's free and it works great.

Atari has their own 80 column generator, the XEP80. It plugs into the joystick port and gives you crisp true 80 columns and a printer port. I have no idea if a VT100 emulator has been written to take advantage of the XEP80.

And you know how painful DEC terminals can be... fireplace@cup.portal.com

I have just purchased Atari Writer Plus and am using it on a 65XE with 2 Atari 1050 disk drives. You are supposed to press "R" in the Proof Reader menu to return to Atari Writer main menu. The Atari Writer disk is in drive 1 and the dictionary disk is in drive 2. The problem is that the program displays the full screen Atari logo and then sits there period. Does any one know if I am doing it wrong or is this a bug.

By the way this is a REAL NICE word processer and my family enjoys using it very much.

Thanks for any help.

Mike

> ....
>
The 800XL was (and yes, still is, as are the "old" 400 and 800) a great machine. But, what don't you like about the XE machines? The difference that most people in net.land complained about when the XE's came out (as I recall) was in the keyboards. Some people prefer the feel (or whatever you call it) of the XL keyboards to the XE. Also, the console keys on the XEs are harder to see and in a different place (which, I admit, caused my wife and I a little trouble until we got used to them. "Coloring" the first letter of each console key's name with a different-color marker on each keytop seemed to help us adapt to the console key "transplantation").

Even if you don't like the new keyboards (which we did, once we got used to them), the XEs are otherwise superior (in my opinion). Note for example, the "complete" video hookups on the monitor output jack, that is, BOTH luma AND chroma are actually wired! This means, that on a 130XE, you can get the best resolution available from any (un-hacked-on) 8-bit Atari on a compatible monitor (e.g. the recently readily available Commodore 1802C).

The extra 64K of RAM (a bit less if you talk to/read Bill Wilkinson et. al.) in the 130XE is no piece of dogdoo either, especially if you have a DOS that supports a RAMdisk in that extra memory (BTW, the OMNIVIEW 80-column chip from CDY [where has he moved to?] supports that RAMdisk with any DOS as long as the DOS isn't hiding part of itself in the "old" XL 16K bank, ala DOS-XL in extended mode). (Granted, a 64K RAMdisk is not huge, but better than no RAMdisk at all! Now if I only had time to program again...) And there is some commercial/PD/? s/w that uses all that memory also (like Synfile XE, though I'm not sure what it uses it for; buffers I guess).

(I won't even go into the OS and BASIC changes [improvements, mostly] to the XEs, mostly because I don't know that much about them :-). Anyone else care to take over here?)

So, what you think? Was the 800XL better than the XE machines? I don't feel that way. How about the rest of you 8-bit users?

Yes, Mike, it can ALL be done! I am using an unmodified Atari 800 to type this very message, while dialed in at 1200 baud and emulating a VT100.

>
> 1) How do you connect a modem to an 800? Isn't there a
> built-in serial port of some kind? Can you use this for a
> modem, or is it needed for disk or printer communication?
>

Originally, the only way to connect a modem to an Atari was through the built-in serial port. ALL Atari 800 peripherals would attach to this serial port, "daisy-chaining" from one to the next. An Atari 850 Interface Module was required in order to convert Atari serial signals to RS-232 compatible signals and connectors. A software handler would boot into memory FROM the Interface Module if it was powered up before the computer were turned on. This is one way your friend can go; this is in fact the way I'm connected right now. It has a certain reputation as the "standard" configuration. Drawbacks: outlay of about $100 for the Interface Module, assuming you can even FIND one; you can't access any other serial-port peripheral (printer, disk, cassette) device while the Modem port is open. Terminal software for file transfer, etc., has to close the modem channel before saving each piece of data, then close the storage (say, disk) device before re-opening the modem.

The last few years have seen many different pieces of hardware and software come out for the Atari 800 and subsequent models, to let the computer use modems without needing the often-expensive-and-hard-to-find Interface Module and its handler. One such device is the "P:/R: Connection" which plugs into the Joystick port and can drive a printer (P:) or RS232 (R:) device through there, using, again, a custom handler

Atari recently (1987?) came out with a 300-baud smart modem which plugs directly into the serial-port daisy chain; if you didn't require 1200 baud I'd say this was the way to go, hardware-wise (write to 'aegnor@bsu-cs' or 'atariman@bsu-cs' - two of my friends here - who have this device). The model number is XM301, I believe, and it comes with a fairly nice TTY program... Atari is supposed to release a 1200-baud version, the XM1201 I think, sometime soon. I'm looking forward to it, as the 1200 baud modm I'm currently using is borrowed from 'atariman'!

> 2) Can you get an 80-column by 24-line display on 800?
> Do you need an add-on board? Where do you get one?
